It will be said, again, that the faith of the Profession in the efficacy of its remedies over diseases has been of late years rudely shaken; that methods of treatment, which have received the sanction of ages of authority, are now regarded as of dubious worth; that the use of drugs has been grossly abused; that great mischiefs have been done through the indiscriminate doings of honourable members of our art. Let all this be granted; but what sort of an apology does it form for the conduct of those who indirectly and surreptitiously patronise this gross deception? We all well know what a revolution has, of late years, come over the practice of medicine; and we know that this better knowledge is to be ascribed entirely to the immense progress which has been made in the pathology, the diagnosis, and the study of diseased processes. All this advance, too, has been made through the ardent labours of the legitimate sons of Medicine. We may well boast that all the great deeds of medicine were done by her true sons. Let the patrons of Homœopathy search history, and tell us what good thing ever came out of the mental degradation implied in the practice of quackeries. I see the names of Harvey and Jenner, and a host of such like worthies, indelibly inscribed on the Edifice of Medicine, but I look in vain for a single name that sparkles brightly in the dead seas of quackery. Let men ponder on this fact.

While the practice of Medicine is undergoing modifications, naturally induced by the advances made in our knowledge, we may well suppose that impostures would flourish and grow apace; but such a moment is not one in which, one would have anticipated, that men could have been found to desert their calling, and basely hold out a hand to catch fruit from the most flourishing trickery of the day.

And is the Surgical patron of Homœopathy less free from blame? He may say, that those on whom he operates need no physic, that he often brings his patients successfully through most serious operations, without administering one grain of physic. This he may truly say. But he cannot affirm beforehand, that even the simplest of his operations will not be followed by symptoms which require the most prompt and energetic remedies; he knows, on the contrary, that they frequently are so followed. Called in to attend to a compound fracture, will he permit his Homœopathic friend to trifle the patient's life away with his globules, when a raving delirium has supervened and is tearing the patient to death? Called in to attend an urethral stricture, will he suffer the Homœopathic patient to undergo the incidental torments of inflamed bladder and kidneys thence resulting, without demanding the administration of remedies which he knows in his conscience will assuredly bring ease and repose to the patient? Will he tacitly suffer the globulistic farce to be played out in such a case? If a sore look ill, or if a testicle be inflamed and the patient hot and feverish, will he not purge with calomel and black draught? Or is it come to this, that he regards a knowledge of the practice of Medicine as a mere expletive in the Surgical art?

This, I take it, is the position he assumes in the face of Homœopathy, because it suits his purposes to do so. Then, let me tell him, that he holds a position in relation to his master Homœopath, ten times more degrading than ever the Barber-Surgeon of ancient days held towards the Physician. The Barber-Surgeon was a mere tool in the hands of the Physician, to do his work; but he was at all events an honest implement; he acted after his knowledge and his conscience. I will leave the Profession to decide what is the term which fits the conduct of an educated Surgeon of this day, who exercises his chirurgical art upon a human being, and leaves the Medical treatment of the case in the hands of an Homœopath. I have used strong terms in this letter, but the one which alone befits him I cannot bring my pen to write.

But whether he be Surgeon or Physician who consorts in this wise with the Homœopath, let him make his choice for the future. Let our Profession plainly tell him that he who is not with us is against us; and show that its voice can reach even to the highest placed amongst us. Time, indeed, is it for the Profession to assert its rights, when some of the leading members of it are found ready to carry out in private what certain of the smallest members of it have been known to offer to do through public advertisement, viz. the treatment of disease by Allopathy or Homœopathy.

This quackery I speak of, like the thousand others which have lived their day, and for the day have disfigured the growth of Medicine, will pass away. What vigour of growth the parasite possesses, it draws not from its own intrinsic powers of vitality. It clings for support around, and sucks its nourishment from, the stately stem of an art which still flourishes after thousands of years of growth. Rent away from that stem, the parasite would perish to-morrow. Stripped of the degree which he dishonestly clings to, the Homœopath would stand forth before the world a simple trickster; while backed by an untrue title, and supported and fostered by members of the Profession itself, he may become the most successful impostor of the day.

I am, &c.

JUNIOR HOSPITAL PHYSICIAN.

London, April 26, 1858.

[To the Editor of the Medical Times and Gazette.]

Sir,—The question raised concerning Homœopathic practitioners is interesting; investigation is needful, and it is well that you have opened your columns with such freedom.

Every question must be treated on its own merits. The public accepts Homœopathy, gulled or not gulled; they like it, and from royalty to pauperism seem rather enamoured of its globules, and nothing-like potions. No doubt this is to be mourned over, but how shall it be helped?

It is an old tale that when there is no case it is good to abuse

the plaintiff's attorney; but the eyes of people are getting open. The public knows something itself. The *Medical Times* abuses the practitioners of Homœopathy. It says they are usually ignorant and illiterate, but the public know a large number of highly-educated and industrious men who have taken up with Hahnemann's dogmas. The *Medical Times* says they are men who have failed in the legitimate practice of their profession; but the public knows many who have been eminently successful before embracing Homœopathy, and have made large sacrifices in changing their mode of practice. (a)

Abuse will not stay the progress of Homœopathy.

But then the *Medical Times* says: "Let us not meet the practitioners of Homœopathy in consultation." I know a case in which a third-rate Apothecary refused to meet a Fellow and late Vice President of the College of Physicians. Such an incident, which may probably recur any day, is simply ridiculous. If Homœopathy had a secret mode of treatment, if its practitioners were men without legal title to practice, the case would be altered; but if members of the Profession are to be precluded from exercising their own judgment, why then there is an end of all future progress. The Homœopath gives medicines on a certain system, and in certain doses, which are not legitimate, and, therefore, legitimate practitioners will not meet him; but, Sir, if we allow this principle, it will be necessary that we have at once a code of laws to regulate the principles and practice of Physics which shall be unalterable as those of the Medes and Persians.

What shall we do? for the evil grows. Why, Sir, do as you propose to do with the Medical Reform question. Let us have a Royal Commission of men beyond suspicion. Let a certain number of wards in our hospitals be placed under the direction of a staff of Medical men composed equally of Old School and Homœopathic practitioners. Let one half of the patients be treated according to the system of the day, and the other half according to that of the Homœopaths—each being cognisant of the other's prescriptions. The result must, of course, destroy Homœopathy, and satisfy the public.

I am, &c.

VERITAS.

Devizes, April 19, 1858.

[To the Editor of the Medical Times and Gazette.]

SIR,—Your journal of late has given us some heroic displays of Allopathic dignity and denunciation of Homœopathic heresy and schism. I am not a Homœopath; but I wish to ask a few questions and make a few observations. Are we to consider Dr. Quin, Dr. Gregory, Dr. Henderson, Dr. Sheridan Muspratt, and a long list of similar men, known to the world as of education and eminent ability, as rogues or fools, because they practise or admit Homœopathy? Has or has not the fierce and often vulgar depreciation of such persons by medical men, done more to advance Homœopathy with the higher classes than not?

If we, the erudite, the infallible, the humane, conscientious, hereditary disciples of the legitimate schools, assume this deep sympathy for the public good, by which so many sufferers are deprived of our valuable services, should we not first and foremost make an onslaught upon such brigands as the Holloways, Morrisons, and their legion, who defy us, who damage public health, and pick the public pocket ten times more than all the Homœopaths,—indeed, it is well known the self-constituted Dr. Holloway can boast an income far beyond any of our great Physicians or Surgeons. To call men of education and character impostors like common quacks, is at least an angry mistake. Homœopathy may have a visionary foundation; but we can never, in this country, put it down by legislation, although we might deal with the insolence, the defiance, and the reckless imposition of common quackery, by having quack medicines licensed only for what good they really may be trusted. As to the Homœopath and the Allopath meeting or not on a case, the matter is determined for them without any consideration of their own,—their difference of creed puts an impassable barrier. By an accident Mr. Fergusson and Dr. Bell might meet in a train, and find they were both sent for to one noble patient—the surgeon to give an opinion and advice of an outward ailment, and the other to prescribe medical treatment; does it follow that these two illustrious savans should fall out by the way,

heartily abuse each other, and leave him to go to the patient who would? It is not uncommon for Medical men in the country to be asked to report cases for Homœopathic patients being at a distance from their advisers, and I see no harm in doing it. Book Homœopathy is much in the hands of ladies; and really I have felt it no joke to hear stated, "since I have adopted Homœopathy, and given the globules to my children, I have not had to send for a Medical man, although we have had influenza, measles, and scarlatina."

I am, &c.

April 26, 1858.

MODERATOR.

[To the Editor of the Medical Times and Gazette.]

SIR,—It must be clear to the thoughtful members of the Profession, that they cannot meet Homœopaths as Practitioners.

Mr. Fergusson simply discharged a duty; but it is not clear that the presence of the Homœopath was necessary to aid his ready hand and skilful head. Your correspondent, *Justus aut Nihil*, has a peculiar notion of the members of the Profession. There can be no need to rave, but there is still less that they should fraternise with the disciples of a dreamy theorist.

There are no circumstances under which a legitimate practitioner cannot be as readily accessible as a globulist. No physis is required to tie the radial artery, or for the other operative procedures mentioned by your correspondent. When people are really suffering, depend upon it they will take medicine.

A clergyman meets a catholic priest in society, and accords to him the courtesies of his station, but here, professionally, their correspondence ceases. Was the practice of medicine a system of error before Hahnemann's day? Is there anything beyond the dreamy twaddle that is called "The Principles of Homœopathy," are its remedies really original? It is but the obsolete dietetic school of the ancient Greeks.

Whenever practitioners as individuals become trimmers to every vagary of their patients, they will earn their reward—contumely and distrust.

There is one duty which the Council of the College of Surgeons owe to their members, viz. that in future all candidates for their diploma be examined in the practice of medicine. Hundreds of men go forth from that College diplomatised; who never seek or obtain the licence of the Apothecaries' Society. It is not just to the public that men vaunting themselves as legal Surgeons, and practising as Homœopaths, should not have given proof of knowledge of legitimate medicine. Let men who occupy the high places in the Profession do their duty, and it is certain that they will command the co-operation and respect of all who honour their vocation.

I am, &c.

G.H.

March 21, 1858.

[To the Editor of the Medical Times and Gazette.]

SIR,—If the Medical Societies of London, as well as those of provincial towns, would follow the example of the Reading Pathological Society, in the matter of irregular practitioners, we should, at all events, know what the great bulk of the Profession thinks of meeting Homœopaths in consultation; we should also know who has high principle enough to refuse to meet men who profess to treat disease in a totally different manner from the one they themselves profess.

For my own part I cannot at all understand how it is possible for two men holding opposite opinions to come to any agreement as to any plan of proceeding from a consultation, unless, during such consultation, one or other of them alters his opinion; nor how a regular practitioner can derive any assistance from a Homœopath, or *vice versa*; and the effect on the public mind, if the public mind reasons upon it at all, must be most perplexing, and I should imagine the conclusion arrived at, which indeed, must be the true one, would be, that one or other of the gentlemen so consulting must be sacrificing his conscience merely for the sake of his fee.

It is plain that a Homœopath, as such, taking a degree of one of our Colleges or Universities, and afterwards practising Homœopathically, must be dishonest (for obtaining advantages under false pretences), and being so, honourable men may refuse to meet him; whereas, if he remains unqualified, we may refuse to meet him on that account; and it is difficult to understand how Homœopaths writing books as they do, can

[Perhaps our correspondent will name these gentlemen.—Ed.]

have the audacity to put M.D. and M.R.C.S. after their names on the title page, and in the following pages state that their system of medicine is directly in opposition to the system inculcated by those very bodies who have conferred these titles upon them.

As regular practitioners are often expected to meet these men in consultation, and often lose friends and money by refusing to do so, and get the reputation of being illiberal and inhuman, I think it will be a great boon to the Profession if you will still agitate the matter until we know what is expected of us under such circumstances, by the heads of the Profession. If some stringent rule, or rather if some understanding was arrived at on this question, there would be more unity among those who follow the truth, and there would certainly be no fear of humanity suffering in any one instance, because every man of common sense would know that he would not be breaking such rule if he relieved a patient really requiring immediate relief, even though a Homœopath was present at the time, if he protested against all interference on the part of the Homœopath, and resolutely refused any consultation with him.

I am, &c.

"QUOD ERRE VIDEOR."

Reading, April 26.

### SPINAL HÆMORRHAGE.

[To the Editor of the Medical Times and Gazette.]

SIR,—I have forwarded you the account of a case which appears to me of considerable interest in a Pathological as well as Medico-legal point of view; if you consider it worthy of a place in your Journal it is at your service.

I was requested by my friend Mr. Barrett to examine the body of a boy, of whose death he gave me the following account:—

On Friday, March 26th, at about half-past two in the afternoon, he was sent for to the Reformatory to James Cowen, aged 15, who had been pushed by a playmate against another boy, who held a shoemaker's awl in his hand. This implement had inflicted a small punctured wound on the left side of the chest, between the seventh and eighth ribs, about three inches behind the nipple. As there were no symptoms present, the directors of the institution thought lightly of the case, especially as it was quite uncertain whether or not the awl had penetrated more than skin-deep. Mr. Barrett, however, wished to be on the safe side, and advised rest and a purgative.

On Saturday morning, when he called, the boy came to him, appearing, to use his own expression, "as gay as a lark." He had spit no blood; felt no pain in the chest; pulse and respiratory murmurs quite natural. In fact, he appeared so well that Mr. Barrett congratulated him on his escape. In the evening his bowels were much relaxed, and he seemed not quite so well. This was attributed to the vigorous action of the purgative. He still complained of no pain in the chest or abdomen. The purging continued all Saturday night, and on Sunday morning he appeared weak, and, looking faint, was recommended to return to bed, which he would not do. He spent an hour in the chapel of the institution, from eight to nine, and some time after this vomited, while sitting by the fire with other boys. He entered into conversation with them, and nothing unusual was noticed in his manner till he fell from his chair, at about eleven. Being then quite insensible and unable to walk, he was carried up to bed, and Mr. Barrett was sent for; but as he was in church, the messenger, unwilling to disturb him, waited till the service was over; so that when he reached the house it was more than half-past one.

The patient was then quite insensible; pulse very quick and feeble; respiration slow; pupils unacted upon by light. After continuing in this state for about three-quarters of an hour, he expired, about forty-eight hours after the injury.

The post-mortem examination, at 8 p.m., on Tuesday 30th, revealed a punctured wound penetrating into the cavity of the chest, and wounding the lower part of the upper lobe of the left lung. This was indicated on the surface of the organ by a purple spot, about the size of a silver penny. In the centre of this was a small puncture, into which a probe penetrated about a quarter of an inch. On cutting into the lung at this part it appeared condensed, and of a deep purple

colour, resembling the coagulum of blood, but only to the extent of a small walnut. The rest of both lungs was perfectly healthy. At the seventh intercostal space, on the surface of the costal pleura, was a small quantity of transparent coagulated lymph, easily separable under what appeared the wound. This was a small puncture midway between the seventh and eighth ribs, and did not injure the intercostal vessels or nerve. The left pleural cavity contained four or five ounces of serum tinged with blood. The diaphragm, as also the pericardium, which contained about a drachm of fluid, were uninjured. With the exception of the lower part of the large intestine, which was slightly congested, the organs of both thorax and abdomen were quite healthy. The brain was somewhat moister than usual, and the lateral ventricles each contain about half a drachm of serum; it, however, presented no other trace of disease. The inquiry which, up to this point, was not most satisfactory in its results, became much more so on opening the spinal canal, for as soon as the first arch was removed a quantity of effused and partially coagulated blood appeared, and on opening the canal further was seen to extend from the third to about the seventh dorsal vertebra. The posterior rachidian plexus of veins was gorged with blood for about the same extent, but no rupture could be detected in any of them, though there was every reason to believe that they were the source of the effusion. The spinal cord itself was softened to the extent of about two inches, opposite the third and fourth dorsal vertebra. The dura-mater, arachnoid, and pia-mater of the cord, as also the medulla itself, were in other respects unaffected.

The rarity of diseases of the spine, or at least the rarity of its detection, renders this case of more than usual interest, more especially when we consider the youth of the patient. Its coincidence with a wound is, moreover, of Medico-legal importance, for had the injury been inflicted with felonious intent, it might have endangered a human life.

Not wishing to encroach too much upon your space by any further remarks on this case,  
I am, &c.  
Brook-green, April 7, 1858.

JAMES KEEN.

### REPORTS OF SOCIETIES.

#### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, APRIL 13, 1858.

Sir C. Locock, Bart., President, in the Chair.

(Concluded from p. 438.)

A paper by Dr. GREENHALGH was read on

#### EXTENSIVE DISEASE OF THE OSSEOUS SYSTEM NECESSITATING THE PERFORMANCE OF THE CÆSAREAN SECTION.

The subject of the paper was a patient in her 31st year, who during her eighth pregnancy, was attacked with symptoms simulating rheumatism, for which she had been treated. During the sixth month of utero-gestation, when she was first seen by the author, she was greatly emaciated and very decrepid, moving about her room with extreme difficulty, and by the aid of surrounding objects. From being five feet one or two inches in height, she was reduced, in the space of a few months, to four feet two inches and three-quarters. Her urine was found to be loaded with neutral triple phosphates, which a variety of remedies failed to arrest. The nature of the case being suspected, a vaginal examination was instituted, which revealed a large amount of pelvic distortion, so great as to render delivery impracticable by any other means than the Cæsarean operation. At the full period of pregnancy, labour spontaneously set in; and notwithstanding every attempt was made to reach the os uteri by three of the eminent accoucheurs who favoured the author with their counsel and assistance, their endeavours proved futile; consequently the operation was performed by the author in the ordinary manner, and a living child extracted. Although the patient was alarmingly reduced in health and strength, and a considerable

amount of blood was suddenly lost, owing chiefly to the placenta being situated immediately under the line of incision through the uterus, still she continued to progress more or less satisfactorily for fourteen days, when rupture of the transverse colon took place, attended with alarming prostration, from which, however, she rallied. Through this opening faeces continued to escape into the abdominal cavity up to the time of her death, which occurred nineteen days after the operation. The author then detailed the results of the post-mortem examination, which showed extensive atrophy of the whole osseous system, besides far advanced fatty degeneration of the numerous tissues submitted to microscopic and chemical investigation. Especial attention was directed to the dried pelvis, the dimensions of which were detailed, and which with the uterus were placed before the Society. The author then referred to the circumstances under which the disease developed itself, the rapidity of the progress, and the insufficiency of remedies to arrest the malady; the form of bones affected, and their peculiar distortion; the state of the urine, as shown by Dr. Beale's analysis; the period of utero-gestation and labour at which the operation was undertaken; the condition of the patient previous, during, and subsequently to its performance; the mode and seat of the incisions; the hæmorrhage and its sources; the position and firm attachment of the placenta in relation to the wound; the presentation of the child; the extraction of the placenta; the propriety of partial or complete closure of the abdominal wound. He then drew attention to the patient's state during the nearly three weeks she lived after the operation, especially to the rapidity of the pulse during the absence of other symptoms indicative of inflammatory action; the rupture of the transverse colon, and the attendant prostration and subsequent rally; and lastly, under the head of treatment, referred to the exhibition of large and frequently repeated doses of opium, to generous diet, and to the effects of ice and stimulants.

Dr. MERRYMAN said he had lately attended a patient in labour under somewhat similar circumstances, who had become gradually (though not so rapidly as in the case described) affected with mollities ossium. He had had doubts as to how the labour would terminate, and he asked Dr. Tyler Smith to see the patient with him. By his advice he (Dr. Merryman) introduced the air-ball, and endeavoured to widen the passage. He was convinced that on that occasion there was a distension of the bones of the pelvis, during the period that the bag was fully distended with air. He was afterwards able to pass his finger more readily than before; the aperture, however, was very small, and he could not ascertain how the labour was going on. He brought on the labour artificially by injecting hot water. They tried to alter the position of the child, so as to bring out the feet first. With great difficulty the child was turned; but, in consequence of the length of the labour, its life was not saved.

The PRESIDENT asked whether the patient had been in bad health.

Dr. MERRYMAN replied, that she had been in bad health for several years, and the bones of the pelvis had been gradually drawing closer together. Dr. Smith had examined the water passed, and found it to contain large quantities of phosphates.

Dr. TYLER SMITH said, the important point was, whether delivery could be effected by any safer means than the Cæsarian section. No doubt there was great deformity existing, but it was difficult to say, from the preparation that had been handed round, whether any other means could have been adopted. It appeared to him that compression had taken place in the bones since the death of the patient; that a process of shrinking, and drying, and diminution had taken place, as indicated by the crackings to be observed in various places. Even now the bones were movable, and when they contained the gelatinous matter, which they must have had in life, he imagined they were still more movable. His impression was, the deformity was not at all greater than that in the case adverted to by Dr. Merryman, in which case they managed to get away the head of the child. It was compressed to a very great extent at the coronal suture, and the child did not survive; but the life of the woman was saved, and she was not exposed to any great danger. The os uteri could not be reached; but they were able, the bones being soft, to introduce the hand, get down the leg, and extract the child, without exposing the woman to the dangers of Cæsarian section. He had had some other cases, though not so severe,

and had found that in all of them it was possible, by pressure, to dilate the pelvic bones to some extent. They were elastic and yielding, as compared with the bones of the healthy pelvis. He should like to ask the President whether he had found that in mollities ossium he could produce any extension of the pelvis during the time of labour. His own impression was that they might, before the labour came on, by air or fluid pressure, dilate the pelvis to some extent in such cases. He should like the President to examine the pelvis, and say whether he did not think there had been some amount of shrinking since death, so that the preparation scarcely gave a fair representation of what had existed in life.

The PRESIDENT said the symphysis pubis was made to lap over, which most probably was not the case during life; and that would make a very material difference in the diameter above, a difference of at least half an inch. Possibly, as the preparation had been handed round, the bones might have been bent more closely together. He had no hesitation in saying that he had delivered cases, not by turning, but by craniotomy, where there was as much difficulty as there appeared to be in the present case, supposing the bones to be expanded to the fullest apparent extent without dislocation. The awkward gait of the patient in the early months of pregnancy, to which reference had been made, must have been caused by the fracture of the neck of the thigh-bone.

Dr. WEBSTER said he should have liked to ask the author, had he been present, why premature delivery was not brought on.

Dr. MACKENZIE said that question appeared to have been fully discussed, and the Cæsarian section having been determined upon, it was thought better to postpone it to the full period of gestation.

Dr. BARCLAY said it should be borne in mind that the author stated distinctly that, when he made his examination, he could only pass the fore-finger of the right hand as far as the first joint on one side, and that he could barely insert the tip of the finger on the other. If that were a true account of the state during life, it exactly corresponded to the condition of the bones as exhibited.

Mr. TAYLOR confirmed the statement of the author as to the smallness of the passage during the life of the patient.

Dr. SMITH asked Mr. Taylor if his hand was passed, or only the finger, into the vagina.

Mr. TAYLOR replied that he introduced only two fingers.

Dr. SMITH said it was impossible to ascertain accurately the state of the pelvis with the finger only. His observations referred merely to the fact of the Cæsarian operation having been performed at the full time, with a pelvis of that character. All accoucheurs would consider the propriety of inducing premature labour in such a case; and, of course, the earlier the operation was performed, the more chance there would be of the passage of the child. He spoke of the operation as having been undertaken at the full time. For himself, he should have no hesitation in undertaking delivery in such a case.

## THE PATHOLOGICAL SOCIETY,

TUESDAY, APRIL 6.

Dr. WATSON, President, in the Chair.

Mr. HUTCHINSON gave the conclusion of a case formerly brought before the Society, of

### CANCER OF THE TESTIS IN A YOUNG CHILD.

Enlargement of the gland had first been noticed when the boy was a year and five months old. Excision was performed on March 3, 1857, when he was two years and a quarter old. The testis, which was then about the size of an adult's fist, was a good specimen of medullary cancer, and was brought before the Society during the former session. The boy regained perfect health after the operation, and remained well for eight months. Symptoms of cancer in the lungs then showed themselves, and progressed very rapidly. Death took place on February 7, eleven months after the operation. At the autopsy both lungs were found most extensively infiltrated with medullary cancer. One small nodule, the size of a small pea, was noticed in the liver, but with that exception there was no disease of the abdominal organs. No return of the

disease had taken place either in the cord or the lumbar lymphatics. It was an interesting fact in respect to the hereditary transmission doctrines that two paternal uncles of the patient had died of cancer of the breast.

**Mr. HUTCHINSON also showed specimens from a case of HYDROCEPHALUS, AND ENLARGED MESENTERIC GLANDS IN CONNEXION WITH HEREDITARY SYPHILIS.**

The patient, a male infant, aged five months, had died of hydrocephalus, which had commenced when one month old. The head was enlarged to thrice its natural size, and the lateral ventricles were found at the autopsy distended with clear serum, their septum being broken down. No evidence of inflammation, or of the deposit of tubercle, could be found within the skull. The specimen brought before the Society consisted of the entire mesentery, the glands of which were almost universally enlarged. None of them were very large, and none contained tubercle. The infant had during life presented most undoubted symptoms of hereditary syphilis, which had disappeared under mercurial treatment. The history of syphilis in its parents, and of the death of their preceding infants from the same disease, was also clear. Mr. Hutchinson remarked that the existence of disease of the mesenteric glands was of interest in connexion with the emaciation so commonly observed in cases of infantile syphilis. As to the hydrocephalus, he could not help suspecting that when it occurred under such circumstances it had more than an accidental relation to the diathesis. He had at present under care a second case of hydrocephalus in a syphilitic infant.

Dr. MARKHAM read a paper on a case of

**RUPTURE OF THE COLON, PRODUCED BY DISTENSION OF THE GASES WITHIN IT.—MALIGNANT DISEASE OF THE SIGMOID FLEXURE OF THE COLON.**

E. C., aged 63, a hard-working woman, who had always enjoyed good health up to about six months ago. She then suffered from swelling of the left side of the belly, from pain, which she referred to the region of the uterus, from flatulence and constipation. When the pain was bad she also felt a numbness and weakness, and twitchings of the legs, which came on with increase of the swelling of the belly. These symptoms continued up to the time of her death, which took place rather suddenly about seven months from the beginning of her illness. Charcoal and pressure carefully applied to the abdomen seemed to give her great temporary relief.

*Post-mortem.*—The abdominal walls were most tensely distended with air. When the cavity was opened air gushed out with extraordinary violence, the walls falling at once down quite flaccid. Six quarts of dark, greenish-looking matter, of the consistence of gruel, were found in the cavity, and two or three more quarts in the lower part of the intestines. In the upper part of the sigmoid flexure of the colon was found a cancerous thickening and contraction of the gut. This part had been forced down into the pelvis, and had formed an adhesion with the upper part of the rectum, giving to the intestine a curve, which must have assisted in impeding the passage of feces. At the upper part of the descending colon a rupture was found, about an inch long, passing across the intestine; the inner and outer coats alone were torn, the muscular fibres being pushed aside. There was not the slightest appearance of ulceration at the part, and merely a flush of redness around the border of the rent, which was clear and well defined. The feces were inodorous; a fact which was explained by the quantity of charcoal which the patient had taken. The muscular coat of the colon was exceedingly thickened, no doubt in consequence of the obstruction in its sigmoid flexure. This rupture of the gut was manifestly caused by the forcible distension of the air within it. No doubt the thickened muscular coat of the colon must have caused unusual pressure upon its contents; and it is possible also that the strychnia, which the patient had taken for some time, might have aided in producing a spasmodic contraction of the muscular coat of the colon.

Dr. MARKHAM also read a paper on

**AFFECTION OF THE HEART, WITH ENLARGED THYROID AND THYMUS GLANDS, AND PROMINENCE OF THE EYES.**

The subject of this affection was a female, aged 26. Nine

years ago she suffered from acute rheumatism, and had been subject to rheumatism ever since. The thyroid gland began to enlarge six years ago. For the last six months she had been under treatment for severe palpitations, and on account of these she came into St. Mary's Hospital in March, 1858. Her eyes were so prominent that she could not close her eyelids; but she never suffered from conjunctivitis. The least exertion or mental emotion brought on violent palpitations of the heart, which were always attended with severe "dull, wearing pains." The beat was like that of the heart of an hysterical person. She was highly nervous. A slight systolic bruit was heard over the whole præcordial region. In the second left intercostal space, close to the sternum, a long rough prolonged systolic bruit was heard, and a thrill felt by the finger; the murmur, though loud, was very limited. This murmur was constantly present. The pulse was always small. Treatment gave only temporary relief. Latterly her breathing became affected, and she died somewhat suddenly, about two months after her admission into the Hospital. The pupils were equal in size; and no throbbing was observed of the thyroid gland.

*Post-mortem.*—The body was very anæmic; the gums were blanched. The thyroid gland was large and firm, embracing, but not compressing, the larynx and trachea; but it compressed the carotid arteries and internal jugular veins. The thymus gland exceedingly large, but healthy in structure, weighing 2½ ounces, passed down in the anterior mediastinum, ending in two lobes; one of these, broader and larger than the other, passed across the pulmonary artery, and apparently pressed upon it. The heart's valves were thickened, but competent; its muscular structure much altered, there being numerous small dots of fibrinous matter scattered here and there in it. The papillary muscles were particularly affected, being partially converted into hard fibrinous matter. Some slight atheromatous spots were observed in the coronary arteries, and a few in the aorta. The lungs posteriorly were in the first stage of pneumonia. The other organs and the vessels of the brain were healthy. The bruit heard evidently arose in the pulmonary artery: it must have been anæmic, or caused by the pressure of the thymus gland upon the pulmonary artery.

Dr. VAN DER BYL exhibited several specimens, and made some

**REMARKS ON SEVENTY CASES OF HYPERTROPHY OF THE HEART.**

The first specimen weighed 30 oz., and occurred in a man aged 33. The aortic valves were covered with vegetations, but the aorta was healthy. The cavity of the left ventricle was 4 inches in length; and about three times its usual size; its walls measured 7 lines near the middle. The second specimen also weighed 30 oz., and occurred in a man aged 62, who had suffered from chronic bronchitis, &c. The cavity of the left ventricle was 4 inches in length; and its wall measured 9 lines near the middle. The valves were not much diseased; the arch of the aorta was dilated to about double its natural size, and involved in advanced atheromatous disease; the pulmonary artery contained distinct patches of atheromatous deposit. The third specimen weighed 36 oz., and occurred in a man aged 28, who had had rheumatism five years before, and had been troubled with dyspnoea and palpitation ever since. The cavity of the left ventricle was 5½ inches in length; its wall measured 9 lines near the middle (15 lines opposite the papilla of the mitral valve); the aortic valves were shortened and thickened, and proved incompetent; the mitral valves were slightly diseased. In the right auricle there was a slender fibrous band, about an inch and a quarter long, one extremity of which was fixed at the so-called tuberculum Loweri, and the other at the Eustachian valve. The fourth specimen weighed 14½ ounces, and occurred in a man aged 42, who had been subject to palpitation since childhood. The mitral orifice was very much constricted, and presented only a crescentic slit; the valves were thickened and calcified; the aortic valves also were shortened, thickened and calcified. In this case there was comparatively little hypertrophy, with extensive disease of the aortic and mitral valves; whereas in the third specimen, which weighed 36 oz., there was scarcely any valvular disease. With regard to the fibrous band in the right auricle of the third specimen, it appears doubtful whether this is a relic of foetal life, or the result of disease. In the Middlesex Hospital Museum is a preparation which

exhibits a similar band; the left extremity of which, however, is fixed to the free margin of one of the tricuspid valves. It occurred in a boy, aged 16, and produced a 'tricuspid murmur.' A third specimen of this kind was exhibited, in which the band was about 2 inches long, and gave off numerous tendrils, which formed a kind of floating network. Hypertrophy of the heart occurred in 70 cases out of 380 post-mortem examinations; that is, in 18.4 per cent. of patients dying from various diseases. In all the cases the heart weighed upwards of 14 oz. in the adult male, and upwards of 12 oz. in the females. Of these 70 cases, 46 were males and 24 females. The average age of the males was 43.3 years; the average weight of their hearts was 19.3 oz. The average age of the females was 41.6 years; the average weight of their hearts 15.6 oz. Some of the principal morbid appearances associated with hypertrophy of the heart in these 70 cases, were: Disease of the aortic valves in 36, of the mitral in 32; in 22 of these, aortic and mitral disease co-existed; vegetations on the aortic valves in 9, on mitral in 5; adherent pericardium in 9; atheroma of aorta in 13, of pulmonary artery in 1; cerebral hemorrhage in 4; bronchitis in 10; phthisis in 7; granular disease of kidneys in 46; cirrhosis of liver in 21, &c. The eight volumes of the "Transactions of the Pathological Society," contain accounts of 40 cases of hypertrophy of the heart, in which the weights are given. Of these 34 were males, and only 6 females. The average age of 31 of the males was 44 years; the average weight of the heart of the 34 males was 22.1 oz., the heaviest weighed 40 oz. The average age of the females was 37.5 years; the average weight of their hearts was 17.5 oz. Disease of the aortic valves occurred in 28, of the mitral in 17; in 14 cases aortic and mitral disease co-existed. From this analysis of Dr. Van der Byl's observations, and of the cases recorded in the "Transactions," it appears: 1. That hypertrophy of the heart occurs in nearly 18½ per cent. of patients dying from various diseases. 2. That it is about twice as frequent in males as in females; or, exactly as 8 to 3. 3. That the average age of males and females is nearly the same; that of the males being 43½ years, and of the females 39½. 4. That in hypertrophy of the heart disease of the aortic valves is more frequent than disease of the mitral; as 8 to 6. 5. That in hypertrophy vegetations are more frequently situated on the aortic than on the mitral valves. 6. That adherent pericardium exists in about one-eighth of the cases; and 7. That granular disease of the kidneys occurs in about two-thirds of the cases.

Dr. PRACOCK brought forward specimens from a case of  
**TYPHOID FEVER FATAL FROM RELAPSE.**

The feature of most interest in the case was that fresh ulceration was shown in the intestines, having evidently occurred during the relapse. A female, aged 19, a servant, residing in Camden-town, was admitted into St. Thomas's Hospital on the 30th of November, 1857. She then stated that she had been ill three weeks. She was taken with cough and pains in the limbs, and general febrile symptoms; but she was too weak and her intelligence too much impaired, for this report to be depended upon. At the time of admission she presented characteristic symptoms of typhoid fever; there was much torpor of mind, delirium, and tremor of the extremities; the tongue was dry and brown; there were sordes on the teeth, a quick pulse, diarrhoea, and an eruption of rose-coloured spots, fading on pressure, on the abdomen and back. On the 19th of December the bowels became much relaxed, and there was blood in the stools, and this continued for three days. On the 12th she began to improve, and on the sixteenth or seventeenth day from admission, and the thirty-eighth from reported seizure, she was convalescent. The pulse had fallen to 92, the bowels were regular, she took her food well, was quite intelligent, and had gained strength. She continued to improve till the 23rd, and then was taken worse, without any assignable cause. The tongue again became dry and brown, the teeth were covered with sordes, and the pulse quick (116) and weak. There was a return of torpor of mind, tremor, and delirium, with vomiting and diarrhoea. On the 29th she had again rallied considerably, but during the evening she passed a large quantity of blood from the bowels, and became collapsed, and died the following morning. There was no fresh eruption on the skin during the relapse. On examining the body the organs were found generally healthy, except the spleen, which was large, the

mesenteric glands, which were large and soft, and the mucous membrane of the large and small intestines, which displayed evidence of old and recent typhoid disease. In the lower part of the ileum, cæcum, and colon, more especially, there were numerous ulcers, some healing or nearly healed, with depressed edges and shallow cavities, or only marked by very light remains of abrasion and puckering of the adjacent mucous membrane, while others were evidently of quite recent formation, having tumid and abrupt edges, and the usual yellow eschars, either still attached or only imperfectly separated.

Dr. Ogle showed a specimen of  
**SPONTANEOUSLY HEALED ANEURISM OF THE INNOMINATE ARTERY.**

The aneurism was of the size of a moderate sized orange and was very firmly adherent to the posterior aspect of the right sterno-clavicular articulation; the sternal extremity of the clavicle being pushed forwards and upwards, and being very greatly enlarged by deposit of new bone. The aneurism, of which a section had been made, was seen to be filled by old standing, partially discoloured coagula, arranged in concentric layers, excepting one very small portion in the centre of about the size of a large pea, where the fibrin was much softened and pulpy. The right carotid artery was filled and obliterated by firm old standing fibrin. The specimen was removed from the body of a man, aged 44, who died of phthisis with vomicae, in St. George's Hospital, under Dr. B. Jones. He was originally a sailor, and on one occasion whilst using great efforts as steersman, during a violent storm, the right arm became, as he thought, frozen, and in a few days after intense pain came on, extending from the right side of the head to the finger ends. He was subsequently treated in various London hospitals for rheumatism of the right arm and shoulder, and was the subject of every conceivable method of treatment. After being in St. George's Hospital a time, pulsation was found on deep pressure at the right sterno-clavicular joint, and dyspnoea followed, the pain being most extreme. He went out of the hospital somewhat better, but returned once more. During his stay in St. George's, the right carotid was found to have become obliterated. Severe head symptoms and insensibility followed, and these gave way to great freedom from pain and uneasiness, so much so that he went out of the hospital again, and learnt a new trade, which for five years he followed. He finally came into St. George's Hospital with symptoms of consumption, and died. There was never any inequality in the pulse of the two wrists, and the heart's sounds were always natural; but up to the last pulsation was felt about an inch to the right of the sternum beneath the second rib.

Dr. OGLE also exhibited a  
**LARGE CYST BENEATH THE VISCERAL LAYER OF PERICARDIUM, COVERING THE POSTERIOR SURFACE OF THE RIGHT VENTRICLE, AND FILLED WITH LAMINATED BLOOD COAGULUM OF OLD STANDING.**

The cyst was flattened in shape and about three inches in length, extending as high as the separation between the auricle and ventricle. To its outer surface at the lower part the parietal layer of pericardium was very adherent, as also was the diaphragm, and on very slight traction being exerted at one portion, the outer wall of the cyst readily gave way. The walls of the cyst were very firm, and thick in most parts. There was no communication between this cyst and any of the heart's cavities, and it appeared as if the blood had been extravasated from some branch of one of the coronary arteries, which in other parts were found somewhat atheromatous. Moreover, in the lower part of the right pleural cavity a large quantity of old standing coagulated blood was found, which had apparently found its way thither from the cyst beneath the pericardium through the parts before mentioned, where the walls were so easily torn through on removal of the adherent parietal pericardium and diaphragm. The specimen was removed from a person of middle age, who had pneumonia of the lower part of the lungs, and who died within a few days of admission into St. George's Hospital.

Dr. MARKHAM read a paper on a case of  
**CYSTIC DISEASE OF KIDNEY.**

A man, aged 48, was brought into St. Mary's Hospital, insensible, having suddenly fallen down in a fit; and died

about two hours afterwards. His wife stated that he had always previously been a healthy man.

*Post-mortem examination.*—His body was that of a fine muscular man, and presented externally no signs of disease. The cause of his death was found to be a large extravasation of blood into one of the cerebral hemispheres, which evidently resulted from rupture of a bloodvessel, the cerebral arteries being all of them highly atheromatous. The heart weighed 21 ounces; its valves were all competent. Both kidneys were studded with innumerable cysts—some of the most minute size, some as large as a walnut—a considerable amount of healthy-looking renal substance intervening between them. The left kidney weighed 21 ounces, the right 16 ounces. The urine found in the bladder when heated became solid through coagulation of albumen in it. The other organs of the body were healthy in appearance. The kidneys were carefully examined by Dr. George Johnson and myself. The tissue was generally healthy; some few of the tubes were denuded of epithelium, some few were shrunk, and some dilated and thickened. The albuminous condition of the urine is not satisfactorily explained by the state of the kidneys.

The case is interesting as showing that serious organic diseases, and that albuminuria, may exist in a person who, to all appearance, is in a vigorous state of health. The hypertrophy of the heart was no doubt caused by the atheromatous state of the arteries at the periphery of the body.

## EPIDEMIOLOGICAL SOCIETY.

MONDAY, APRIL 5, 1858.

Dr. BABINGTON President in the Chair.

The Annual Report of the Council was read by Dr. McWILLIAM.

A paper was read by Dr. MILROY on

### THE SICKNESS AND MORTALITY IN THE FRENCH ARMY IN THE EAST FROM 1854-6.

The first French troops, 8000 in number, landed in Gallipoli on the European side of the Dardanelles, at the end of March 1854. They were camped out a few miles beyond the town, which, like all Turkish towns, abounds in fifth and unwholesomeness. Two or three buildings within the walls were at first occupied for a Hospital, but they had soon to be abandoned. This was invariably the case throughout the whole campaign, whenever native buildings were made use of, without previous thorough purification. By the beginning of June, the force assembled was from forty to fifty thousand strong. The sick rate did not exceed 15 per 1000 of strength. In consequence of the threatened fall of Silistria the greater part of the troops were sent on to Varna, to be near the seat of war. With the increased heats of summer, the sick-list had gone up rapidly, and bowel complaints had become very prevalent, and began to assume a choleraic character. Sporadic cases of malignant cholera occurred in the last week of June both at Varna, and Gallipoli, and Constantinople. The disease became more prevalent and severe in July at every station. Many of the crowded transports from France and Algeria had cases on board during the voyage out. The disease seems to have manifested itself in the south of France that year about the same that it did in Turkey. M. Scrive, the principal Medical officer of the French army, (from whose instructive "Relation Medico-Chirurgicale de la Campagne d'orient," most of the details of the present paper are drawn,) was satisfied that the cholera was not imported by the arrival of troops from France, as has been alleged, but that it developed itself on the spot, although the frequent disembarkation of predisposed and infected troops aggravated the mischief. At the end of July, while the choleraic influence was prevalent everywhere, the unfortunate expedition to the Dobrudscha, the notorious malarial district on the south side of the Danube, was undertaken. The Medical staff was not consulted upon the occasion, and no special hygienic precautions were thought of by the military authorities in command. The results were most disastrous. Within a week from leaving Varna, the most advanced division had been more than decimated by a terrible explosion of the pestilence, its deadly power being aggravated by the fatigue and privations to which the troops had been subjected. The loss of life was

immense. On its return to Varna, death and sickness had reduced the effective force of the division by one-third of its number. The mortality from cholera alone, during the months of July and August, amounted to between five and six thousand, and this, too, before a shot had been fired. There had been also much sickness from other diseases at the same time. The sites of many of the camps were bad, the tents were crowded, and much of the food was unsuitable for the then condition of the troops. When the army sailed on the 7th September for the Crimea, its health was considered tolerably good. Cholera had nearly ceased; there were but few cases during the voyage, or for several days after landing at Eupatoria. The battle of Alma was fought on the 20th; the French, 23,000 strong on the occasion, had 300 killed, and 900 wounded. Cholera increased immediately after the battle, in consequence, it was believed, of the armies halting for a couple of days on the field, strewn with the putrid carcasses of hundreds of horses, and polluted with other abominations. Excessive fatigue and indifferent food had also something to do with the increase. The officers on this occasion suffered as much as the privates; the food of both was the same, and they were exposed to the same privations. In October, the first month of the siege, cholera occasioned a fourth part of the entire sickness in the camp, and two-thirds of the whole mortality. The newly-arrived troops invariably suffered most. This was uniformly the case during the whole campaign. Between a seventh and an eighth part of the entire force, now 46,000 strong, was sent into hospital during the month by sickness alone. Scurvy had begun to appear. Complaints were made of the food. Hitherto the weather had been favourable. In November things became worse in every respect. After the terrible storm on the 14th the weather was much more inclement. Cholera had subsided, but scorbutic diarrhoea and dysentery had much increased. The death-rate to cases rapidly went up. Wounds did not now heal favourably. A good many cases of severe frostbite occurred. The shelter and clothing of the men were quite insufficient; they had only *tentes d'abri* to cover them. Throughout December and January the sufferings of the men were terribly aggravated. They were still without proper tents or suitable clothing, and the supplies of food, such as it was, were scanty. Many were frozen to death, and several thousands were sent into hospital from severe frostbites. A third of the cases proved fatal. Scorbutic disease prevailed throughout the camp. In January, out of a nominal force of 78,000, upwards of 15,000 were either sent into the ambulances on the field, or shipped off to the hospitals at Constantinople. In February the state of things was even more dreadful. Besides scorbutic diseases, utterly intractable, typhus and hospital gangrene were frequent in the hospitals, and the medical officers could do nothing to prevent their spreading. The more favourable weather in March and April gave the opportunity of effecting various improvements in the condition of the troops, both sick and well, and with these the health of the men became somewhat better; but the continuing want of fresh vegetables kept up a scorbutic taint among all the old troops. The cholera, which had been in abeyance during the winter, began to reappear in April, and it advanced with the advancing season. The great increase in May was doubtless owing, in a great measure, to the large reinforcements which arrived this month, as new comers were always more liable to being attacked than others. Hence the necessity for special precautions under such circumstances, an important point in military hygiene. The erratic movements of the disease in the camp were quite inconsistent with the idea of their being dependent upon transmission by contagion. Notwithstanding the constant arrivals of vessels with cases on board at Kamiesch, it never spread to the population there. June was a very sickly as well as a very sanguinary month. Nearly a sixth part of the army, then 122,000 strong, was sent into Hospital by disease and wounds. The proportion of admissions from the latter cause was as one to between three and four from the former. Cholera reached its acme this month. Besides an increase of bowel diseases and malarial fever, scurvy was again on the increase. For the previous two or three months the men had collected a good deal of the wild "*taraxacum*," of which they made a salad. The summer heats had now withered it up, and they were left without a substitute. So prevalent was the disease in July, that M. Scrive says, that "all our old soldiers are at this time more or less scorbutic." In August the number of

fresh cases of scurvy taken into Hospital was double that in July. Cholera had declined, but there was still an enormous amount of sickness, chiefly from bowel complaints and fevers. Nearly 11,000 sick were shipped off this month to Constantinople, and between 15,000 and 16,000 admissions into the ambulances took place. In the battle of the Tchernaya on the 16th, the French had about 300 killed, and 800 wounded. Sebastopol fell on the 8th of September. Five thousand wounded were sent into the field hospitals on that memorable day. There were as many in the ambulances at the time, so that Hospital accommodation for at least 10,000 patients was required. The huts and tents were crowded, and, ere long, hospital-gangrene became very prevalent. Scurvy all the while continued to add a large quota to the sick-list, and cholera had not ceased to attack the fresh arrivals. The first rude weather in November found the French army as unprepared for another year on the bleak heights of the Crimea, as on the preceding year; and as winter advanced, and no adequate preparations for the shelter and proper clothing of the men were made, the Medical officers dreaded a renewal of all the horrors then experienced. Their fears were doomed to be realized. In consequence of the enormous crowding together of the men, both sick and well, under their miserable tents, or in their subterranean hovels, typhus fever acquired this season a power of intensity which hitherto it had not displayed, and added terribly to the amount of sickness and death, from scurvy, bowel diseases, hospital-gangrene, and other disorders, aggravated, if not induced, by the sufferings and destitution to which the men were exposed from want of proper shelter and food. Thousands after thousands were every month sent off to Constantinople, and still there was never room enough in the camp hospitals for the thousands that were continually thrust into them. Within three months typhus alone caused 20,000 admissions, and 10,000 deaths. The medical men could do nothing but to look on and despair. Many of them fell victims to the pestilence. When peace was concluded, at the end of March, there is good reason to believe that the French army could not muster more effective troops than half its nominal number; such were the enormous deductions which typhus and scorbutic disease occasioned. But it was not in the camp alone the fever caused such dreadful losses to the service. The hospitals around Constantinople had been allowed to become crowded to overflowing, and this too without any due precautions having been taken to secure a corresponding increase of ventilation, so as to maintain anything like purity of air for the inmates. They became in consequence perfect pest-houses, where not only the sick and wounded did not recover, but where disease was engendered, and where hundreds and thousands admitted for other maladies, perished from typhus generated within the wards. Far better, said Dr. Milroy (who had inspected the French hospitals both in the camp and at Constantinople), that the sick, and especially the sick from fever, should be scattered about in large courtyards, or on any open clean and dry ground, and be put under canvas or any shelter, however imperfect, than that they should be accumulated together in buildings where there is not an adequate amount of space for each inmate, and where a pure atmosphere cannot be maintained by the constant renewal of unpolluted air by night and by day. Without this simple and essential measure, every other precaution will be of no avail. The total losses by death of the French army, during the campaign, may be estimated at little if at all short of 80,000. Of this number 16,000, or a fifth part, were caused by the direct casualties of war; 7,500 men and officers having been slain in action, 8,500 having died of gunshot wounds and other injuries. Four-fifths of the deaths were, therefore, occasioned by diseases chiefly of the zymotic class, which are all capable of being mitigated and controlled, if not entirely prevented, by a wise hygiene. Besides the losses by death, 65,000 more were invalided from the effects of sickness or of wounds.

A discussion followed, in which Mr. Chadwick, Dr. Greenhow, and Dr. Waller Lewis took part.

**MENTAL PATHOLOGY.**—Prince Alexander Torlonia has offered to found at his own expense a Chair of Mental Pathology in the University of Rome, with the sole stipulation that Dr. Monti, director of the Asylum at Ancona, should be the first Professor.

## M'KINNELL'S SYSTEM OF VENTILATION.

It is a device by which ventilation appears to be reduced to a system, more perfectly than it has ever been before, so that the arrangements necessary to effect it can be easily introduced at a small cost into old houses, and into lower stories as easily as into apartments near the roof. At a still less cost also it may be provided for in houses which are being built. To understand the current about to be noticed, it is to be observed as a law in relation to tubes and circular orifices leading into a confined space that air tends naturally to flow inwards by the tops of the orifice or along the sides of the tube, and that the outgoing air goes up the centre, and when there is a difference of temperature between the air passing out and that passing in, the outgoing and ingoing currents become proportionably more strong and decided.

DESCRIPTION OF THE PLATE.

A represents the upper storey of a house, with the Ventilating Apparatus carried vertically through the roof. A tube of zinc, *aa*, or other suitable material, is fixed in the ceiling of the apartment, *bb*. Inside this tube, and concentric with it, is placed a smaller tube *d*. These tubes communicate with the external atmosphere at different levels, the vitiated air rising up the central tube and passing off at the higher level; while the fresh air enters the annular passage, between the inner and outer tubes, at the lower level, and descends into the apartment below. Both passages are defended from rain, soot, &c., by perforated zinc or wire gauze, and provided with suitable valvular mechanism for moderating the currents—that of the outer passage, in the form of a projecting flange—*ii*, serving to deflect the downward current of fresh air, and spread it out horizontally, so as to render its action imperceptible, while the ascending current may be regulated by a simple throttle valve. These valves are acted upon by cords passed over pulleys, and taken to any convenient point.

B shows the mode in which lower apartments are ventilated. The arrangements are similar, except that the fresh air enters the annular space horizontally by *aa*, and the vitiated air is discharged by *d*, which is connected with the centre tube of the Ventilator. The horizontal part of tubes *a* and *d* may embrace any portion or the whole of the space between two joists and the floor (*ll*) and ceiling (*bb*). The vertical portions may consist of flues in the walls. In both cases, the arrows readily indicate the direction of the ingoing and outgoing currents.

The above description may serve to give a general idea of this system of ventilation: but various modifications are made to adapt it to different buildings; to all kinds of which it will be found applicable, as well as to ships, railway and private carriages, &c.

In the extremely simple contrivance we have just seen, advantage has been taken of these laws; and the action has been facilitated by artificially relieving the currents ascending and descending from mutual contact. This has been done by a concentric arrangement of two tubes, one tube being placed within the other, thus separating the inner from the outer current. In the practical application of this to a room, a circular hole is made in the ceiling, of dimensions proportioned to the size of the apartment to be ventilated. This aperture in the ceiling is the end of a tube opening outwards to the external air. Another tube is introduced into the centre of this one, also opening into the external air and into the room; and this concentric arrangement of the two tubes is so devised that the capacity of the central tube shall be equal to the annular space enclosed between its outer circumference and the inner aspect of the external concentric tube. Simple, efficient, and natural channels are thus provided for the influx of fresh air, and for the removal of contaminated air. The simple action is determined in a certain definite direction, and which is always constant; namely, the ingoing current of fresh air passed by the outer concentric annular space, while the noxious emanation produced by respiration and other processes of life are simultaneously carried off by the inner tube. To avoid currents of air blowing down by the annular space, the end of the inner tube is turned outwards in the form of a flange, and the portion of the end bearing this flange is made to slide up and down within certain limits, so that when pushed close up to the ceiling, the orifice or inlet for the air is completely shut if desired, or modulated accordingly. The immediate effect of this flange is to break the force of the current of air, which impinges against it, whence it is reflected to the ceiling. Upon the ceiling it is scattered and broken, and having thus swept across the roof, it gradually descends to the floor in broad and imperceptible currents. Towards the inner tube a stream of air is constantly rising from the interior of the apartment, carrying off the vitiated air. The slightest possible elevation of temperature within a room immediately institutes the flow of the currents in and out. The action is thus almost automatic, the supply of fresh air being regulated by the demand caused by the outgoing currents. Under ordinary circumstances this arrangement appears to furnish a simple and very efficient system of ventilation, for it is exceedingly rare in this country that the temperature of the air outside a building approximates with sufficient closeness to the temperature within as to counteract the influence of the natural law on which the action of this beautiful system is based. We consider this system as well worthy of extensive trial. It is simple, it appears to be of universal application, its action is consistent with natural laws, and with its good properties it seems to blend no evil ones, which, in the words of a cotemporary, "is saying an immense deal for a ventilator."

A model of four school-rooms, ventilated by McKinnell's system, may be seen in the Museum of the Society of Arts, John-street, Adelphi.

## PARLIAMENTARY INTELLIGENCE.

### HOUSE OF LORDS.

#### SALE OF POISONS.

Lord CAMPBELL asked whether it was the intention of the ministry to introduce a bill this session to regulate the sale of poisons?—Earl Derby said the Home-Secretary had put himself into communication with the Pharmaceutical Society with a view to learn their views on the subject. The introduction of a bill would depend upon the nature of the communication, which had not yet been received. On Monday next he hoped to be in a position to give a definitive answer to the question.

### HOUSE OF COMMONS.

#### THE PUBLIC HEALTH ACT.

Mr. ADDERLEY moved for leave to introduce a bill to amend the Public Health Act of 1848. Several continuance acts had been passed, under the operation of the last of which the General Board of Health would cease to exist in the month of September next. He had under those circumstances felt

it to be his duty to introduce a bill upon the subject, and in doing so he had done his best to deal with it upon a permanent footing. The general principle of the measure which he was about to ask the House for leave to introduce was one, the object of which was to decentralize the whole system; to allow the General Board of Health to expire in September, and to enable all those towns which desired to possess the power of self-administration to constitute local boards through the medium of meetings of owners and ratepayers, two-thirds of whom must consent to the adoption of such a course; it being open to town councils or commissioners, who fairly represented the inhabitants of large towns, to exercise similar powers in that respect as the owners and ratepayers to whom he had just adverted. He also proposed that the Boards which might be constituted under the act, as well as all the local Boards now in existence, should have the amplest powers of self-administration extended to them, and should be no longer subjected to the necessity of referring to a central Board in London. Those powers of self-administration would, however, be placed under proper check by granting to individuals who might feel themselves aggrieved by the action of those local Boards a power of appeal, and also by rendering it necessary that they should annually undergo re-election. The appeal would be made to the Secretary for the Home Department. The general Medical functions of the Board of Health, as contrasted with its towns' improvement functions, he proposed to deal with in a separate measure, the former being distinctly central and Governmental functions, the latter essentially local.

The motion was agreed to.

## MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at the meeting of the Court of Examiners on the 19th inst. :—

DEARDEN, JOHN, Accrington, Lancashire.  
EATON, JAMES, Grantham, Lincolnshire.  
GARNER, JOHN, Birmingham.  
GRACE, HENRY, Kingswood-hill, Bristol.  
HAYWARD, H. H., Queen Anne-street, Cavendish-square.  
MOULD, GEORGE WILLIAM, Sudbury.  
SADLER, HENRY GEORGE, Wandsworth.  
STOKES, PAUL HENRY, Peckham-rye.  
TURBER, G. H., Torriano-avenue, Camden-road-villas.  
VAUDREY, JOHN COSHAM, St. Agnes, Cornwall.  
WEAVER, FREDERICK POYNTON, Chester.  
WILLEY, JOSIAH, Bristol.

Also on the 23rd instant :—

BRAITHWAITE, ROBERT, Whitby, Yorkshire.  
BURLAND, BENJAMIN, Fairfield, near Liverpool.  
BURY, JOHN WALTER, Wandsworth.  
EASTON, JOHN, Russell-square.  
HOWITT, FRANCIS, Newcastle.  
HUGHES, JAMES, Middlewich, Cheshire.  
JENVEY, JOHN H., Mortimer-street, Cavendish-square.  
LEACH, HENRY, Wisbeach, Cambridgeshire.  
M'COULL, GEORGE, Newcastle-on-Tyne.  
OLDMAN, JOHN, Gainsborough, Lincolnshire.  
RIDING, WILLIAM STEER, Euston-square.

APOTHECARIES' HALL.—Names of gentlemen who passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, April 22, 1858 :—

BURLAND, BENJAMIN, Fairfield, Liverpool.  
GRAVES, FREDERICK GEORGE, Southam, Warwickshire.  
HARLEY, JOHN, Ludlow, Shropshire.  
PRATT, THOMAS OCTAVIUS.  
TOLLER, EBENEZER, Great Wilbraham, Cambridgeshire.  
WATSON, WILLIAM S., Southampton-street, Bloomsbury.

#### DEATHS.

ASSHETON.—On the 17th instant, at the residence of his daughter, Mrs. Ingram, Queen-street, Chester, T. H. Assheton, late of Liverpool, aged 83.

**BARNETT.**—On 3rd March, at Colusa, in California, Robert Augustus Barnett, M.D. Coroner and Physician to the County of Colusa, aged 36.

**BULMAN.**—On Tuesday last, at Bishop Wearmouth, William Bulman, M.R.C.S. and L.S.A. 1849; of Villiers-street, Cumberland, aged 39.

**DUCHESNE.**—On the 28th instant, in Lime-street, Spital-square, Clarke Duchesne, M.D. aged 59.

**GREGORY.**—Professor William Gregory, of Edinburgh University, died on Saturday evening, after a protracted illness. He was one of a race of distinguished Scottish Professors, his father having been the celebrated James Gregory, Professor of Medicine in the same University, and several of his ancestors having held a high place in the academic literature and science of Scotland. William Gregory was a very able and accomplished chymist. He was a favourite pupil of Liebig, and was the translator of some of his master's works from German into English, besides being the author of several treatises of great merit. He successively filled the chairs of Chymistry in the Andersonian Institution, Glasgow; King's College, Aberdeen; and Edinburgh University, having been appointed to the latter in 1843. He was very little past the prime of life, but had been long in a state of ill health, and during part of last season was unable to fulfil his duties personally. He leaves a widow, and a son named after his great master.

**JONES.**—On the 8th instant, at Glen Helen, Carnarvon, William Jones, M.D. aged 81; late of the 1st, or King's Dragoon Guards.

**MILNER.**—On the 10th January, at Turawong, New South Wales, Robert H. Milner.

**DR. RHUDERS,** Physician, has set to music the palpitations and irregular beatings of the heart of a female who is a patient in the Hospital at Upsal. "This disease, written in musical notes, with quavers and semi-quavers, forms a kind of waltz, and is one of the greatest curiosities of pathological science."—*Swedish Paper.*

**GENERAL BOARD OF HEALTH.**—The total expense of printing the weekly returns of the Board of Health ("Health, etc. of the Metropolis"), from the first number to the 26th of March last, amounts to £399 5s. 1d., in addition to the postage of 250 copies circulated weekly. Salaries to the amount of £8680 were payable to the officers of the Board of Health for 1857, including one of £1450 to the president (up to the 24th of September), £1500 to the Medical officer (Mr. Simon), £1000 to the secretary, and £1000 to the chief inspector superintending.

**FIVE CHILDREN AT ONE BIRTH.**—On the morning of Monday last, a woman, named Elspet Gordon, residing in Rothes, gave birth to three male and two female children. The three boys were born alive, and lived till the following morning, but the two girls were stillborn. The births were premature, being in the sixth month; but, what is very extraordinary, all were full grown for the period of gestation; nor is this the most surprising circumstance in the case, one of the boys having actually two front teeth when he came into the world. Dr. Dawson, Rothes, attended the woman, who, we are happy to say, is doing wonderfully well.—*Elgin Courant.*

**CLIMATE OF SILLOTH.**—It is probable that few persons are aware of the advantages which Silloth affords in respect of climate to the invalid, or indeed to any person who values an equal temperature. It appears from the weekly "weather table" in the *Times*, that the range of temperature at Silloth in the preceding week was less than any other place mentioned, with the solitary exception of Helston, a town in the south-west of Cornwall, and the difference in favour of Helston is only 1.9 deg. The *Times'* report states that "the range of temperature was only 21 deg. at Helston, and 22.9 at Silloth, while it was 37.9 at Tottenham, 38 at Leicester and High Field House (Nottingham), and 38.5 at Manchester." This is far from being an unusual occurrence, and the fact is of importance.

**THE SEX OF EGGS.**—The Académie des Sciences publishes in its "Comptes Rendus" the title only of a note addressed to it by M. Génin, who thinks he has discovered the

clue to the secret whether the contents of an egg be male or female. M. Génin sums up his proposition thus:—"There are two classes of poultry traders; first, those who want female eggs only, to rear hens for the sake of their eggs; and secondly, those who want male eggs only, to produce cocks and capons to eat. Now, if these eggs are not, *a priori*, distinguishable, the natural results of hatching must be accepted as a matter of necessity, whence there arises a dead loss for each of these classes of poultry breeders. Without any view to trading profit, I have long attempted the solution of a problem, which professional poulterers pronounce insoluble. Long have I remained in incertitude. At last I discovered my way, by starting from the fact that the bones of women are smoother and cleaner in their texture than those of men, as may be seen from a comparative examination of the skeletons of the two sexes. Applying at the outset this point of comparison, I am able, after three years' study, to state with assurance, that all eggs containing the germs of males have wrinkles on their smaller end, while female eggs are equally smooth at both extremities." Such is M. Génin's conclusion. At this season of the year it would be very easy to ascertain by experiment whether the test has any foundation in fact or no.

**MEETING OF THE MEDICAL REFORM COMMITTEE OF THE BRITISH MEDICAL ASSOCIATION.**—A meeting of the Medical Reform Committee was held at 3, Waterloo-place, Pall-mall, on Friday, April 23rd; Sir Charles Hastings, M.D., in the chair. There were also present:—G. Bottomley, Esq.; Sir John Forbes, M.D.; G. W. Hastings, Esq.; A. Henry, M.D.; B. W. Richardson, M.D.; F. Sibson, M.D.; G. Southam, Esq.; J. Stedman, Esq.; and G. Webster, M.D. The minutes of the last meeting were read and confirmed. Mr. Cowper's Medical Bill was again taken into consideration; and the following amendment, in addition to those already proposed, was unanimously agreed upon; its object being to guard against the institution of a third grade in the profession. "That any person, who has passed the examination to be instituted by the Council for general practice, shall be allowed to assume the title of 'surgeon.'" The Committee subsequently had a long interview with the Right Honourable W. Cowper, at which there were present:—Sir Charles Hastings, M.D.; G. Bottomley, Esq.; A. Henry, M.D.; E. Lankester, M.D.; G. Southam, Esq.; J. Stedman, Esq.; and G. Webster, M.D. The various amendments proposed were fully discussed and explained to Mr. Cowper, who expressed his readiness to have such alterations made in his Bill when in Committee of the House as would meet all the wishes of the Medical Reform Committee already mentioned; as well as to provide that the examination for general practice should in all cases include medicine, surgery, and midwifery. The following resolutions were thereupon passed unanimously:—"That, the interview with Mr. Cowper having been highly satisfactory, and he having expressed his desire to carry out the alterations proposed by the Committee, a petition, signed by the Chairman on behalf of the Committee, be presented to the House of Commons in favour of Mr. Cowper's Bill." "That the Secretary be desired to write at once to the Secretaries of the Branches, urging them to call meetings, and to petition in support of Mr. Cowper's Bill."—Alexander Henry, M.D., Secretary.

**THE ATTEMPT ON NAPOLEON III.**—M. Tardieu sums up an elaborate article in the April No. of the *Annales d'Hygiène*, with the following conclusions:—1. The victims of the attempt, known to exist, and whom he has officially visited, amount to 156—a number certainly below the reality. Of these 9 have died, 6 were very severely wounded, 18 were severely wounded, 56 had wounds of a medium gravity, and in 67 the wounds were slight. 2. The totality of the wounds amount to 511, many of the persons having more than 10, and 2 of them more than 20. 3. With the exception of 5 or 6, which were the result of accidental contusions, or lacerations produced by the breaking of windows, they were all produced by the innumerable fragments scattered on every side by the explosion. 4. Most of the wounds penetrated deeply into the organs, and in spite of their slight apparent extent gave rise to the production of considerable lacerations and injuries. 5. These wounds, in consequence of the irregular and heated condition of the projectiles which gave rise to them, and of their depth and narrowness, were complicated with effusion of blood, phlegmon,

and neuralgic pains, which added much to their gravity. 6. Nine persons have succumbed, and 6 others have been, or still are, in danger of life. 7. The incapacity for personal labour, resulting from the wounds produced by this explosion, will in general be prolonged; and some of the wounded will certainly remain the subjects of incurable infirmities.

**THE GENERAL HOSPITAL, VIENNA.**—The official report of this institution for 1886 has been recently published. The whole number of patients treated within the Hospital during that year amounted to 25,403, viz. 15,233 males and 10,170 females; and of these there were—

	Males.	Females.	Total.
Dismissed cured . . .	10,233	6,339	16,572
„ improved . .	1,224	754	1,978
„ incurable . .	383	389	772
There died . . . .	2,162	1,791	3,953
Remained under treatment	1,231	897	2,128
	15,233	10,170	25,403

Enumerating some of the diseases in the order of their respective frequency, we find the following numbers:—Syphilis, 2090 cases (878 m., 1212 f.); typhus, 1824 (1231 m., 593 f.); gastro-intestinal catarrh, 1821 (1071 m., 750 f.); tuberculosis of the lungs, 1616 (1006 m., 610 f.); itch, 1346 (1148 m., 198 f.); catarrh of respiratory organs, 1246 (842 m., 404 f.); rheumatism, 686 (435 m., 251 f.); cholera, 665 (320 m., 345 f.); inflammation of the lungs, 584 (390 m., 194 f.); small-pox, 511 (270 m., 241 f.); ague, 500 (386 m., 114 f.); ophthalmia, 476 (286 m., 190 f.); pleurisy, 405 (270 m., 135 f.); congestion of the brain, 321 (195 m., 126 f.); peritonitis, 273 (55 m., 218 f.); disease of joints, 228 (137 m., 91 f.); caries and necrosis, 207 (140 m., 67 f.); emphysema of the lungs, 186 (132 m., 54 f.); the puerperal process, 175; disease of the heart, 164 (87 m., 77 f.); hæmoptysis, 145 (106 m., 39 f.); neuralgia, 145 (76 m., 69 f.); paralysis, 136 (75 m., 61 f.); congelation, 133 (120 m., 13 f.); “degenerations of female genital organs,” 128; gout, 117 (55 m., 62 f.); scorbutus, 106 (90 m., 16 f.)

## VITAL STATISTICS OF LONDON.

Week ending Saturday, April 24, 1888.

### BIRTHS.

Births of Boys, 894; Girls, 916; Total, 1810.  
Average of 10 corresponding weeks, 1848-57, 1598.

### DEATHS.

	Males.	Females.	Total.
Deaths during the week . . . . .	575	569	1144
Average of the ten years 1848-57 . . . . .	547.9	505.6	1053
Average corrected to increased population . . . . .	...	..	1159
Deaths of people above 90 . . . . .	...	6	6
Deaths in 15 General Hospitals . . . . .	26	18	44

## TO CORRESPONDENTS.

*Dr. Hamilton Roe's* paper on the treatment of Pleural Effusion is in type, but is unavoidably postponed.

Papers are in type by *Dr. Elliottson* and *Mr. Newman*, and letters by *Dr. Whitehead*, *Mr. Byrne*, *Mr. Keem*, etc. Several anonymous letters on the Encouragement of Homeopathy have been set aside, as the writers have not sent their real names. We never insert letters in this Journal without having the name of the writer in confidence.

*Cæsus*.—Chomel has left three millions of francs, about £120,000.

*M.D.*—It would be very premature to speculate upon the probable successor to *Professor Gregory*.

*A Physiologist*.—It is said that *Dr. Pavey* has recently discovered that the liver is not a sugar-forming organ. A paper by him is about to be presented to the Royal Society, which may probably alter materially the conclusions drawn by *Bernard*.

*Mr. H.*—The charge is one so evidently trumped up, that it has been dismissed by the magistrates. We think it better not to notice it further than to give a word of caution to our readers, never to examine women of disreputable character in the absence of some other person.

### CHLORODYNE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—*Mr. Davenport* has exhibited less hardihood of assertion in his last letter than in any of the previous ones. He formerly proclaimed that *Dr. Collis Browne* had discovered a new alkaloid, which, in combination with perchloric acid, formed chlorodyne. Now he says that it contains “an alkaloid new to therapeutics.” Mark the qualification, not new to science, but new to therapeutics. I now wish to make a suggestion to those members of the Profession who have conscientiously given testimonials in favour of chlorodyne. Let them compare the effects produced by chlorodyne and those resulting from the exhibition of the preparation made according to the following formula:—Dissolve 8 grains of the hydrochlorate of morphia and 20 grains of gingerine in half-an-ounce of alcohol, and the same quantity of chloroform. This formula is not intended to produce a preparation similar in its physical properties to chlorodyne, for it contains neither peppermint nor sugar in any form. The object of the addition of these substances to chlorodyne is merely to disguise its true composition. But while disguising, the addition renders the chlorodyne an ingredient, if not dangerous remedy, by reason of the separation of its components into distinct strata. In the formula which I have suggested, on the contrary, the combination is perfect, and the resulting comparison is a clear homogeneous liquid.

If any of your readers will try the above experiment, it will do more to prove the real nature of chlorodyne, so far as its therapeutic action is concerned, than a thousand assertions of *Mr. Davenport*, and a thousand counter-statements of one who still deems it wise to subscribe himself,  
CHENEVE.

April 26, 1888.

COMMUNICATIONS have been received from  
*Dr. Bence Jones*; *Professor A. von Graefe*, Berlin; *Sir Charles Lockett*; *Dr. Sieveking*; *Chancellor*, Vice Chancellor, and Fellows, University of London; *Dr. Remak*, Berlin; *Dr. Symonds*, Clifton; *Master and Wardens*, Society of Apothecaries; *Mr. Prescott Hewitt*; *Dr. Hamilton Roe*; *Dr. Hærold*, Birmingham; *Mr. Field*, Brighton; *Mr. Stokes*; *Mr. Rivers*; *Mr. Dryland*; *Mr. Brenner*; *Dr. Andrew Clark*; *Dr. Henry*; *Mr. Rogers*; *Dr. Camps*; *Mr. Hughes*; *Mr. Barlow*; *Dr. Austen*; *Mr. Prettly*; *Mr. Weedon Cooke*; *Mr. Wood*; *Mr. H. Landon*; *Dr. H. Downes*; *Mr. T. Windsor*; *Mr. Grey*; *Mr. J. Pritchard*; *Dr. Granger*; *Dr. R. Aldridge*; *Mr. Crawshaw*; *Mr. Dillon*; *Mr. Price*; *Mr. Coxeter*; *Mr. Gill*; *Mr. Haviland*; *Juvenis*; *Dr. McWilliam*; *Mr. Penny*; *Mr. Reed*; *Dr. Camps*; *Mr. Smith*, Southampton.

## APPOINTMENTS FOR THE WEEK.

May 1. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m.; Charing-Cross, 1 p.m.  
ROYAL COLLEGE OF SURGEONS, 4 p.m.: *Professor Quekett*, “On the Vertebrata.”

MEDICAL SOCIETY OF LONDON, 8 p.m.

ROYAL INSTITUTION, 2 p.m. (Anniversary).

### 3. Monday.

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.; Orthopedic Hospital, 2 p.m.  
EPIDEMIOLOGICAL SOCIETY, 8 p.m.: *Dr. Camps*, “On Diphtheria, or Pseudo-membranous Sore Throat.”  
ROYAL INSTITUTION, 2 p.m.: (General Monthly Meeting).

### 4. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.  
ROYAL COLLEGE OF SURGEONS, 4 p.m.: *Professor Hewett*, “On Tumour of the Head.”  
PATHOLOGICAL SOCIETY, 8 p.m.  
ROYAL INSTITUTION, 3 p.m.: *J. P. Lacaita, Esq.*, “On the History of Italy during the Middle Ages.”

### 5. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Orthopedic Hospital, 2 p.m.

### 6. Thursday.

Operations at St. George's, 1 p.m.; Middlesex, 12½ p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.  
ROYAL SOCIETY, 8½ p.m.  
ROYAL COLLEGE OF SURGEONS, 4 p.m.: *Professor Hewett*, “On Tumours of the Head.”  
LINNEAN SOCIETY, 8 p.m.  
CHEMICAL SOCIETY, 8 p.m.  
HARVEIAN SOCIETY, 8 p.m.: *Mr. Weedon Cooke*, “On Scrofulous Disease of the Testicle.”

### 7. Friday.

Operations at the Moorfields Ophthalmic, 10 a.m.; Westminster Ophthalmic, 1½ p.m.; Great Northern, 2 p.m.  
MEDICAL SOCIETY OF LONDON, 8 p.m.: (Council Meeting).  
WESTERN MEDICAL AND SURGICAL SOCIETY OF LONDON: Council Meeting, 7 p.m.; Annual Meeting and Conversations at 8 p.m.  
ROYAL INSTITUTION, 8½ p.m.: *J. P. Lacaita, Esq.*, “On the late Earthquakes in Southern Italy.”

## ORIGINAL LECTURES.

## GULSTONIAN LECTURES FOR 1858.

AT THE

Royal College of Physicians.

By JOHN ADDINGTON SYMONDS, M.D. F.R.S.E.

Consulting Physician to the Bristol General Hospital, &amp;c.

## ON HEADACHE.

## LECT. III.

THE Treatment of Headache may be discussed under the same heads as those under which I have endeavoured to describe the disorder.

1. *Of the Treatment of Headache as the accompaniment of organic Disease.*—Although this kind of headache might seem from the permanency of its cause to be susceptible of but little relief, this does not always hold good. If pain is by no means a necessary attendant on organic lesions, and if even when it does occur it is far from being constant, and is, at all events, liable to periodical exacerbations, it is plain that there is an element independent of the structural disease, which element may be amenable to treatment. It may be that in addition to structural disease there is congestion or inflammation, which causes the pain, and requires local depletion; or it may be only neurotic irritation, which comes and goes, and which may be benefited by a special anti-neuralgic treatment. Long ago Dr. Bright detailed cases which, by periodicity of pain, had assumed a neuralgic character to so great a degree as to excite hopes of recovery, and which were greatly relieved by full doses of quinine.

Indeed, there is no reason why the treatment of structural lesions of the brain should be exceptional to the treatment of organic disease in general, which is most productive of alleviation when the remedies administered are such as would be successful were the disease of a functional nature only. The same anodynes which quell the pain of gastralgia are resorted to for the relief of carcinoma ventriculi. And as the palpitation caused by nervous disturbance is quieted by digitalis, ether, prussic acid, and aconite, we find the same agents available in the palpitation which attends upon hypertrophia cordis. At the same time it is not to be denied that structural disease may suggest a speciality of treatment for the pain which depends upon it. A permanent pain confined to one spot, and believed to be dependent on chronic disease in a limited part of the encephalon or its membranes, will often be best met by counter-irritation, such as that of an issue, or a permanent blister.

2. *The Treatment of Hyperæmic Headache.*—In former times the first and leading idea in the treatment of active hyperæmia would have been the management of bloodletting. As to the modern reserve in the use of this remedy in the treatment even of the pure phlegmasiæ, I am one of those who think that the change of practice has been determined more by the altered type of disease, than by altered views of pathology and therapeutics. Doubtless we had learned to economise the expenditure of blood since that heroic age of which Gregory was the representative; we had learned to economise it by a more vigorous and skilful employment of various auxiliary remedies, especially of antimony, mercury, and opium. Between the period when it was no uncommon thing to bleed six or seven times in the course of an inflammatory attack, and these days when patients under like disorder often escape even a single venesection, there was a transition period when one or two bleedings, with a leeching or a cupping, followed or accompanied by calomel, opium, and antimony, were found sufficient for the cure. This degree of change was, it seems to me, fairly traceable to an improvement of our art. It resulted from a better knowledge of the precise nature, and especially of the stage of the disease under treatment, of the influence of remedies according to the stage of the disease, and also of the physiological operation of medicines. But with regard to the present minimum use, if not abstinence from what used to be considered indispensable, I think it has resulted mainly from the more æsthetic character of disease. Even allowing that some

expectancy of method has been engendered by observing that certain heretical methods have been somewhat less dangerous and disastrous than might have been anticipated (though they carry with them, Heaven knows, enough of peril and mischief), I feel confident that were phlegmasiæ to present themselves in the same force as that which belonged to them in former times, we should attack them with the same weapon, though I also believe that our thrusts, being delivered with more dexterity, and directed by a better knowledge of the vulnerable points of our antagonists, would need to be fewer than in the energetic warfare of our somewhat truculent ancestors.

But though such is my opinion, shared with many of my brethren, as to the cause of the present treatment of inflammations, I hold a different view as to the change of practice in many other diseases. The expectant treatment of fevers, and the treatment of chronic disease, and, indeed, of all disease not acutely phlogistic, may be said to have been changed by the improvement of our pathological knowledge.

The limitation of bleeding in diseases of the brain, even when the character is inflammatory, has been for many years made matter of warning by some of the wisest and ablest of the pathologists of the day. An increased or a lessened degree of pressure is equally injurious to the organ; the former, not only by interference with the function, but also by the risk of extravasation and exudation; the latter is more suddenly dangerous, because the effect on the brain itself is extended to the heart, the enfeeblement of whose action at such a time may bring instant death. The experiments which I related in the first lecture, show that in the animals operated upon, the diminution of blood in the brain was far more deleterious than the excess.

But it is not my province to discuss the treatment of inflammation of the brain, nor yet of simple hyperæmia. Were I considering the latter in its relations to apoplexy, the case would be very different. But I have to deal only with hyperæmia, as a prominent fact in certain kinds of headache.

Now in that form which we first surveyed, and in which blood has been too often and too urgently attracted to the brain, in its overwrought activity, under the influence of intellectual excitement or of passionate emotion, it is obvious that before all things, and without which all other means can avail but little, there must be rest. An easy thing to recommend, but how hard to be obtained! For this is not a case of pressing anxiety, in which the appropriate treatment, whatever it may be, is eagerly adopted. But to convince statesmen, or those who are engaged in the toils and competitions of professional and commercial life, that they must lie by, in order to escape the occasional headache, which comes from over-excitement, is not so easy. What course then is to be adopted, when the natural cure by repose and recreation cannot be obtained?

These are the cases in which remedies, that might otherwise be dispensed with, become almost inevitable. The effect of cooling applications to the scalp, of frictions along the spine, of pediluvia, of active purgatives, should be tried first; but if they do not avail, blood may be drawn from the vicinity of the head by leeches or cupping. I am very much in the habit of directing in such cases the application of leeches to the anus, not only because a smaller amount of loss is sufficient, but also because we thus obtain a revulsive effect, and lessen the portal plethora, which is often an aggravation of the cerebral congestion, and thus imitate one of the compensations of nature, by which the disorder of one part removes that of another. Is it a confession of weakness that one cannot produce relief without shedding blood? If it be, it is a weakness which belongs to nature, among whose sanatory processes, epistaxis and hæmorrhoids take conspicuous places.

The management of position is an obvious point, and of great importance in the treatment of congestion of all kinds. In the busy part of the day the thinker or writer may find advantage in standing at a desk, instead of sitting and leaning over a table. And in the recumbent posture it will be very useful to raise the shoulders and head, and at the same time by means of a sufficiently reverse inclination of that part of the bed on which the pelvis rests, to provide against the tendency to slide downward. Often by this simple arrangement a morning headache, from passive congestion, has been warded off.

But when the immediate congestion has been removed, and

by whatever method, there is the more difficult task of removing or lessening the disposition to a return. This is not the place for discussing hygienic methods, of which we hear quite enough from our hypochondriacal patients, as well as from the philanthropic popularizers of medical science. All the measures resorted to for maintaining an equilibrium of circulation operate by inducing an equable or proportionate amount of the various functions, or by causing a preponderance of some particular function. The latter is the most common. How often are we tempted to smile at the self-deception, set going in the first instance by some fashionable jugglery, the self-deception of the energetic hygienic seeker of health, and prosecutor of what he calls natural methods of cure. Suggest a dinner-pill or a seidlitz powder, and his face is convulsed with a fanatical pharmacophobia! His soul abhors the doing of such profane violence to the processes of nature! No—he has been brought to the knowledge of more excellent ways. He traverses hill and dale with the utmost speed of pedestrianism, panting, palpitating, perspiring at every pore, emitting clouds of vapour from his lungs, consuming incredible amounts of nerve-force and muscular tissue, and he thinks that all that he has done is pure gain, and no loss; or he every morning and night spends precious time in scouring his skin with every new modification of the ancient *strigil*, till he has left scarcely an epithelial cell older than yesterday's growth, and forced such an exhalation from the tegumentary surface as was never contemplated in the normal physiology of his system; or he spends as much time in his baths as if he had been born a Batrachian; or he walks about, curiously padded with humid envelopes, which are, by a textural necessity, gradually converting large portions of his skin into mucous membrane; or he is in his cold foot-bath or sitz-bath, sedulously reducing the capillary circulation of the parts subjected to this treatment, to a state of passive hyperæmia; or, with intemperate draughts of cold water, he soaks his tissues, and dilutes his liquor sanguinis, till half his blood-cells are burst by endosmotic distention (according to a process ably explained by Dr. Owen Rees), and he becomes pale and sodden in aspect, because anæmic. In all these various actions, some of them of indubitable value, he is sustained by the fond delusion that he is only helping nature, and manifesting how he rejoices in the liberty of that faith which eschews drugs and doctors. In his simplicity, he is ignorant that he has been tampering with his organization far more actively and extensively than if he had swallowed a minute portion of a substance which has the effect of slightly increasing the discharges from those organs which are the readiest outlets of the system.

Headache from acute hyperæmia of the brain, without inflammation or fever, is by no means so often met with as that passive and chronic form which is left by long-continued over-exertion of thought, or strain of feeling. In this form the treatment is more complicated than in the other, and it may need to have mixed with it one or more of those remedies, which we shall speak of directly as applicable to nervous headache; but, in so far as the vascular element is concerned, the chief object is to restore the lost tonicity. It may be requisite first to produce some diversion by a few leeches to the neck, or behind the ears; or to the temples, the operation of which remedy, as we endeavoured to point out in a former lecture, seems to be effected through the medium of the nervous connexions of the vessels. But in some subjects of this headache it may be desirable to spare even a few drops of red blood. Few, however, are too weak to bear the discharge of a small blister on the back of the neck, which scarcely ever fails to afford relief for a time to this species of headache. Either tepid sedative lotions or cold applications may be administered to the scalp, according to the state of the nerves. And I may here venture to remark, that as a derivative process for relieving congestive states of the brain, I do not think it easy to over-estimate the value of counter-irritants applied to the epigastrum, and, indeed, to the whole abdominal surface. For such affections as we are now treating of, it has long been my custom to order sinapisms, and lotions containing turpentine and pyroligneous acid, and sometimes blisters, to be applied to this region. I have observed the efficacy of counter-irritation thus applied, in the comatose affections of children, and not unfrequently with an agreeable surprise. But the great point is to help the surcharged vessels to relieve themselves by their own contractility—and it is for this purpose that wine, and ammonia, and camphor are so serviceable;

or even decided tonics, such as zinc and iron. The use of such medicines, I need not say to this audience, requires tact and watchfulness, for we have to deal with an organ, whose nerves are put too quick to take offence at remedies of this class.

The headache dependent on congestion of venous origin, while it is chiefly to be met by such treatment as abates the congestion, whether by position of the body or by relief to cardiac or pulmonary obstruction, may, like the other kinds of congestive headache, require a specially anodyne treatment, partaking of that which I shall speak of directly as suitable to the nervous headache. For as such venous delay as occurs in these cases is in a large number of instances unattended with pain in the head, it is clear that when pain does occur there must be a nervous element calling for special treatment. In the use of anodynes in such cases, we have chiefly to be on our guard against increasing by their operation some of those very states which produce the venous congestion.

3. *Treatment of Nervous Headache.*—I hasten now to the consideration of the treatment of nervous headache, that kind of which I have adopted the popular appellation, and which I have described as consisting of a painful affection of the nerves of the brain. And first, as to the removal or alleviation of the immediate attack. It is rare for us to succeed in cutting short an attack, that is, stopping it in mid career, or at the very onset; but we are not without means of greatly abating its violence.

The case is one for a skilful use of anodynes; and I know of no form of pain which offers wider scope for the exercise of ingenuity in the combination of these remedies, and in the mode of administering them, as well as of patience in varying them, till the form and dose have been ascertained which suit the individuality of the case. I need not say that nothing marks the sagacious physician more surely than his faculty of quickly discerning the specialty of the patient submitted to him, so that he may see how the operation of a general therapeutic law must be limited in its application to a particular instance. But in the sufferer from headache it is all but impossible to divine the particular susceptibility of anodynes. And the physician who might very quickly perceive how far his patient's special organism might be likely to tolerate strong antiphlogistic or actively stimulating treatment, might be quite at fault in guessing whether a headache would be relieved or increased by a dose of opium.

The difficulty in administering opiates for the relief of headache is partly explained by what ensues after taking them for mitigation of pain in other organs. We do not doubt our ability to quell the pain of gastrodynia, enterodynia, or toothache, at least for a time, by an adequate dose of opium; but we know the reproach which is often thrown upon us by the patient, who with an aching head and sick stomach, assures us that he has only exchanged one kind of misery for another. This effect of opiates is worthy of a moment's discussion, not only because it is a headache, and therefore within our subject, but also because it is obviously related with the sedative treatment of headache in general.

After a dose of opium sufficient to induce sleep for several hours, the patient may feel upon waking a frontal headache, dull or sharp, accompanied with nausea and vomiting. It closely resembles what is called "a sick headache," and it may last for several hours. It is somewhat like what is complained of after intoxication, excepting that in the latter instance thirst is more prominent. Though there is probably more or less of cerebral congestion consequent on narcotism, the pain can scarcely depend upon that state. We have seen how any excitement of the brain, whether emotional or intellectual, is capable of inducing a painful state of the nerves of the brain. Therefore it is not surprising that anything which so seriously interferes with the sensory ganglia as to compel them to sleep for a certain time, should occasion pain, when the soporific effect has passed off. That there may be some sympathetic influence from the abdominal organs, which have also been tampered with, is very possible, since in some persons the disagreeable consequences are averted by combining an aperient, especially a mercurial dose, with the opiate. But this does not always answer; and I believe that the disagreeable and painful symptoms result from the action of the opiate on the nervous centres. Some persons are so constituted that within an hour or two after taking the narcotic, instead of being sent to sleep, they suffer the same

symptoms of distress, with the addition in some instances of extreme faintness.

It is a problem yet to be solved why narcotics should affect persons so differently. Few constitutional infirmities demand our pity more than the incapability of taking opium without detriment. With many no inconvenience whatever ensues. The paroxysm of pain has been subdued, sleep induced, and no discomfort of any kind is experienced. But seeing that such is the fact, however explained, we cannot be surprised that it should be difficult to administer narcotics for the alleviation of headache.

In many persons the attacks are too frequent to admit of such frequent recourse to doses of sufficient strength for the reduction of the pain. In others they occur in the daytime, and though capable of causing great discomfort they hardly warrant a withdrawal from the avocations of the day, in order that the subjects of them may submit to anodyne operation. But when the case is either severe enough to lay the patient aside, or when it comes on in the later part of the day, there is no reason why the opiate should not be resorted to. My belief is, that we are over-cautious in the use of these remedies for nervous headache. From an exaggerated fear of inducing congestion, we resort to the feeble agents, which are seldom found to be of much avail, and discourage the patient for the trial of more efficient medicines. I confess that for acute pain, I place very little confidence in henbane, hemlock, and lettuce, and hops. If the attack is to be met by narcotics, we should try first one or two grains of opium, or an equivalent of morphia combined or not with calomel or blue pill. In some persons the opium acts more kindly in conjunction with camphor; in others, with a saline draught. But if opium or its alkaloid cannot be resorted to, there are other efficient anodynes which may be appealed to; such are aconite, belladonna, and cannabis indica. Of these, aconite has been in my hands that which may be most relied on: the difficulty is really in its power. There must be enough, but it is more easy to pass from what is sufficient to what is excessive, and therefore dangerous, than in the case of any other narcotic. A little too much opium, we know the worst of. Even with belladonna it is only temporary delirium, or blindness that we have to dread; but a very slight excess of aconite puts the patient in peril by the depression of the heart's action. It may not be amiss to relate an example of the caution requisite in the use of this powerful drug. For a lady who had for many years suffered intensely from attacks of headache, I prescribed the alcoholic extract. The remarkable relief which she derived from this medicine made her anxious to have it always at hand. The dose to which she had become accustomed was half a grain in a pill, and she was allowed to repeat the dose once after two hours if the pain persisted. She took a supply of such pills with her into the country, and she was in the habit of resorting to them as occasion required, with great benefit. But one day, when she was engaged to a dinner party, at some distance, she was attacked with her usual headache a few hours before the time of going out. She hoped to be enabled, by the use of the pills, to keep her engagement. Not finding so much relief as usual, she took a second pill, and was much better; but just before stepping into her carriage she determined to make quite sure of a pleasant evening, and therefore swallowed a third pill. Before she could arrive at her friend's house, she was taken frightfully ill; the carriage was stopped at a cottage by the road-side, and for many hours she was in great danger, with all the symptoms of aconite poisoning.

I usually direct a certain dose of Fleming's tincture (from one to two minims), to be repeated after two or three hours if needful; or one-eighth or one-sixth of Morson's alcoholic extract. In some cases the effect is marvellous. The instances, however, in which I have seen most good result from aconite have been those in which there has been a more chronic species of pain—a constant soreness or disposition to ache. In these a small dose administered thrice daily has been found very salutary, whether combined with tonics or taken singly.

In these cases, again, I have known very great comfort ensue from the use at bedtime of a combination of salines, nervines, and ether. Thus in one of my patients whose brain seems to be always on the verge of aching, such a mixture is always at hand, and rarely fails to avert a threatened fit of pain, though it would be inadequate to the sup-

pression of it when fully formed. Chloroform inhaled will relieve or remove a headache; but its effect is too transient to be of much avail. I have given it by the stomach in its pure form, or as it exists in chloric ether, and sometimes with immediate dissipation of the pain; but the direct anodyne operation is uncertain, and I have sometimes doubted whether the good effects might not be due quite as much to the rubefacient action on the mucous membrane of the stomach, as to the narcotic influence on the sensorium.

The external use of anodynes might be oftener appealed to than it is. When discussing sympathy in relation to the production of pain, I adverted briefly to impressions of temperature on the scalp, and indirectly to anodyne applications, and I expressed a strong opinion that the media of communication are the vascular nerves. I know not in what other way to explain the relief afforded to an aching brain by the application of a pad, soaked in a mixture of warm water and laudanum, to the forehead and temples. This measure is preferable to the employment of stimulating liniments, which, besides the inconvenience attending their use, may do harm by exciting the capillary circulation of the scalp, and by sympathy that of the interior.

In some cases great alleviation is derived from the use of sinapiams or other rubefacients applied to the spine; but it will be generally found when this is the case, that a certain amount of vascular disorder is added to the nervous pain, either as an effect of this, or as the concomitant result of a common cause. But when the pain is more purely nervous, and occurs in a person of high neurotic sensibility, the irritation of the cutaneous nerves may add to the distress instead of lessening it.

But, in addition to the decided narcotics, we have a useful class of agents conveniently grouped under the term nervines. Thus, there are, in the first place, the dietetic nervines, tea and coffee, which are invaluable in the minor degrees of nervous headache, especially when it has been the result of fatigue, either mental or bodily. There is, however, some danger in their use, for they not only dispel the pain in question, but they also recruit the nervous power in the brain so thoroughly as to tempt the patient to return too quickly to the very exertions which have done the mischief. But I am not acquainted with any agents which equal these substances in the power of removing the headache, without leaving inconvenient results. And as their physiological operation is so purely cerebral, restoring the intellectual faculties, and ministering to the sensation of personal well-being, as well as lessening any sad emotions, we have here an additional presumption, were any required, that this headache is seated in the nerves which are immediately related with the molecular action of the brain.

The medicinal nervines are also of use, and chiefly valerian, camphor, castor, and the fetid gums. Of these valerian is at once the most efficient, and the most easily taken, whether as an infusion, or in the form of volatile tincture. But these substances are less beneficial as remedies for an attack of pain than as correctives of the neurotic sensibility which gives rise to them.

This latter treatment may be said to be prophylactic to the attacks, and curative of the diathesis, and it is of far greater importance than that which merely contemplates the removal of the present pain. It is superfluous for me to talk to this assembly of the methods of correcting this diathesis by air, diet, and exercise, or by removing those faults in the digestive organs, or in the uterine system, which have induced it. Nor shall I discuss all the various tonic and other medicines conducive to this end which have been recommended. I shall confine myself to those of which I have had most experience, and which have best prospered in my hands.

There are two which stand far in advance of the rest—Quinine and Arsenic. Iron will do much when there is an obvious deficiency of the red corpuscles of the blood, in conjunction with the diathesis in question, but its value is not so specific as that of the remedies which I have named.

The *modus operandi* of quinine in the cure of ague and of nervous pain, is not without mystery. Were it only a remedy for the cure of that remarkable series of phenomena comprehended under the name "intermittent fever," a comparatively simple hypothesis might present an adequate key. One might begin with presuming that the malarious poison in the blood induces a certain change in the fluid, analogous to the process of fermentation, and that after the eliminative action of the skin, the blood returns to its former condition, with reten-

tion of enough of the poison for producing in a definite period a like process, the very poison being, in all probability, capable of multiplication in the blood; for were it not so, how could the disease remain for months after removal from the malarious source? Admitting such a theory of the disease, it would not be difficult to append to it the hypothesis, that quinine destroys the poison, or prevents it from developing that change in the composition of the blood which eventuates in periodical fever. But quinine is as certain a remedy to the neuralgia which follows a catarrhal attack, or that which is the consequence to a slight blow on the head; cases in which there is no reason for presuming a chemical vitiation of the blood. If the former hypothesis would fit the facts or the philosophy of *ague*, it will not account for the cure of neuralgia.

The operation of this substance, indeed, is so unequivocally exerted on the functions of nervous substance, and with no direct proof of its affecting the composition of the blood, that one would be rather tempted to frame an hypothesis which should bring the cure of *ague* within the scope of a neurotic process.

In an admirably reasoned argument by Mr. Paget, in a lecture on the rhythmical action of the heart, strong grounds were offered by that eminent physiologist for the belief that rhythmical actions depend on processes of molecular growth, occupying definite periods of time. If this be true of physiological phenomena, is it not likely to be applicable to pathology? In those neurotic affections of periodical recurrence, neuralgia, asthma, epilepsy, etc., may it not be that a portion of the nervous substance in some central part suffers an error of growth, which occupies a certain period, perturbs the natural function of the part for a certain time, and ceases, till a new growth has been developed, and runs its course in like manner. I have a patient who every day is the subject of the following attack, and has been so for the last eleven years, without one day's intermission. At 4 p.m. she is seized with clonic spasms of the left arm and the left side of the neck, which last for three hours, and then subside. No mental impression, no opiates, no tonics, no baths, no diet, no change of air, no galvanic currents, no chloroform inhalation, nor whatever the wit of any doctor has hitherto devised, has succeeded in preventing the attack. Once by chloroform inhalation I succeeded in cutting short the paroxysm; but the remedy was worse than the disease. The only remedy which has lessened the violence and duration of the fits is quinine in large doses taken every day. Great hopes were built on arsenic; but the mucous membranes were intolerant of this agent.

Now the periodicity of such an attack is perhaps no greater a mystery than the periodical evolution of nerve-force in the nerves of the heart, if we presume the growth in an abnormal form of a portion of the nervous centre related with the motor nerves in the subject of this singular excitement. Tendency to recurrence of like action is a well-marked attribute of nervous substance, and implies the ready establishment of new forms of growth and action; and it lies at the root of habit in sensation, motion, and thought. Whether in health or in disease, new changes of life and action in the nervous system easily become permanent. Were it not so, what would become of progress and education?—A morbid habit is the continuation of a casual abnormal action. A strong impression is made on the nerves of the heart, and the rhythm of the pulsations is changed: from that time the change may continue. The nervous structure retains its new mode of growth and action: it is an excess of that tendency which belongs to nervous substance in general. An infinitesimal molecule of brain undergoes a change in the production of a thought; and from that time forth, so long as its life endures—in other words, as long as memory is intact—the molecule grows in the same form, undergoing an everlasting series of births and deaths, but maintaining its identity by its perfect similarity of reproduction. And so, as I have said, a new phase of being and action may be impressed on a portion of the nerve centres connected with sensation and motion, and may become permanent. When this occurs easily—when new modes of action are more easily impressed on some than on other individuals, such persons have a neurotic diathesis, a liability to nervous disorder.

A morbid habit is the perpetuation of what should be a temporary state and action; and it argues a diseased tendency to assume so readily a new condition.

A medicine which breaks the habit may be a substance that

nips the new growth, compelling the part to return to its former development. It is like a new element introduced into a soil, destructive of particular organisms. Such may be the operation of quinine, arsenic, zinc, copper, and the vegetable nervines.

I am not so ambitious as to endeavour to construct a new theory of intermittent fever, but I strongly surmise that in the progress of discovery there will be another reaction from the modern excess of humoralism towards a modified and improved neurological pathology, and that new forms of molecular growth in nervous tissues, evolving abnormalities of nerve-force, or new forms of nutrition in secretory tissues, will be discovered, deriving, perhaps, their pabulum from altered blood, but which altered blood will be only one of the series of changes.

Allowing, however, that intermittent fever consists mainly in toxæmia, it is not difficult to understand how in the districts where the poison is rife, there have been noticed in different seasons alternations of that disorder with purely neurotic affections. What, after all, is blood disease? Is it a mere chemical change, such as is effected in an inorganic fluid by the introduction of a new element? Chemical change there may be, but there must be far more of change in the growth and life of those organic cells which form so large a part of the fluid. A poison which may at one time act on sanguineous cells, and interfere with or modify elimination, so as to produce the phenomena of fever, may at another time have a modification which affects vesicular neurine, and occasions neuralgia and strange spasms. Those who are familiar with the history of epidemics must be well aware how interchangeable are fevers and nervous diseases. Wild maniacal dances have followed close upon black pestilences, neuralgia upon *agues*, etc.

Whether tonic medicines, which act chemically, are restorative or catalytic, it is probable they must enter into and take part in the cell-life, whether of the blood or the tissues.

Modern researches, especially those of M. Briquet, into the physiological operation of quinine, go to prove that its special influence is exerted on the nervous system, and that in large doses it depresses rather than excites the principal functions of that system. It is therefore conceivable that if a new form of life has been produced in that system by the operation of a malarious poison, or by any other cause, such an agent as quinine may alter and destroy it. At a certain hour in the day certain nerves begin to ache, and the pain continues for several hours, and then subsides. There must be either in the periphery or in the central termination of those nerves, some new development of nerve-life. Large doses of quinine are swallowed, and the pain appears with diminished force, and in time departs.

Without pursuing any further speculation on the *modus operandi* of these medicines, which are at once tonic, anti-periodic, and anti-neuralgic, I now proceed to observe that quinine appears to me to be of all remedies that which is most extensively and constantly serviceable in headaches, whether strictly nervous, or neuralgic. It at one time helps to remove that irritable condition of the nerves, which makes them take offence at anything unusual in the degree or kind of cerebral action, or at what is occurring in distant organs, and at another time it proves subversive of that very condition of nerves in which the paroxysm of pain consists. It would be less frequently productive of disappointment were it given more liberally and more unflinchingly. Small doses will not avail. And we must be prepared to set aside, or to pacify the fears of our patients, who from the peculiar sensations in the auditory nerves are beset with phantoms of plethora and apoplexy.

If the case has been of recent origin, three grains of quinine thrice daily will usually be a sufficient dose. But if it has been of long standing we must double this quantity, and in some instances ten grain doses must be administered thrice in the day.

Many substances may be advantageously combined with the quinine in order to render it more agreeable to the stomach, especially sedatives, such as extract of hemlock and of hops. I generally administer it in the form of pills, as being more convenient, and less disturbing to the stomach. When the liquid form is used we may add hydrocyanic acid if needful.

Other combined substances may be auxiliary to the specific influence of the quinine, as in the well-known formula of quinine, compound galbanum pill, and hemlock.

Every one to whom I am speaking is familiar with that peculiar affection of the hearing which is complained of by those who take quinine in large doses. It is often, as I have hinted, so troublesome as to deter the patient from persevering with the remedy, especially when, as is common with those who suffer headache, there is an impression on the mind that the vessels of the head are disposed to fulness. It may be a reason for moderating, but not for withdrawing, the remedy.

We have seen when considering the probable seat of the pain in headache, that the ganglionic nerves which accompany the blood-vessels, and are distributed over the membranes and the substance of the encephalon, are the nerves affected. Now if one thing be more distinctly proved by observation than any other, as to the action of quinine, it is that this substance lowers the frequency of the heart's pulsations. This must be effected through the nerves which determine the rate and rhythm of those pulsations, and which are ganglionic. There is here therefore an analogical reason for expecting that quinine may exert a special influence on those nerves which accompany the cerebral vessels.

Next in importance to quinine as a remedy for headache, comes Arsenic. It is not surprising in endeavouring to account for its medicinal action, whether as a remedy for ague or for neuralgia, we should think of its poisonous power, and therefore presume it to be catalytic, or destructive to some *materies morbi*. Whether its action is so purely catalytic, or whether it consists in disturbing and overcoming abnormal forms of growth in the tissues, is difficult to determine. But while we know that in the normal state of the body it produces only too appreciable effects on the mucous membranes, the skin, and the nervous system, we need not look further for the wonderful control which it exercises over diseases of the skin, and over obstinate neuralgic affections. The very extent of its power is an inconvenience in the employment of this substance.

The form of headache in which I have found it most efficacious, has been not so much that which springs from an excessive irritability of the cerebral nerves, as that which comes in distinct paroxysms, and at regular intervals. These are cases in which, after the termination of a paroxysm, the nervous matter grows gradually again into that form which eventuates in a paroxysm. This growth is destroyed by the arsenic. If the hypothesis of a toxic agent be preferred, an agent requiring a certain time for its elaboration, and then for its destruction in the paroxysm which it has induced, we may say that the arsenic has in some way prevented the formation of the agent, perhaps by a quasi-chemical process.

In the administration of this medicine I have preferred small doses—three or four minims, largely diluted, taken thrice daily, and continued for periods of time varying from two to four months.

A long interval separates the degree of value possessed by these two remedies for headache, from that which belongs to any other agents. Still there are other remedies, not without importance, to which we may be driven by the idiosyncrasies of our patients. According to my own experience, the first in this class is Zinc. The oxide and the sulphate have to be given for a long time before they produce any decided effect, but the patience of the physician and of the sufferer will generally be rewarded, especially if a steady and well-graduated augmentation of the dose be enforced, as the stomach becomes more tolerant of it. To eke out the time, to gain temporary advantages satisfactory to the feelings, and confirmatory to the confidence of the patients, until the more permanent good has been effected, it is well to combine the zinc with some neurotic cordial. Camphor avails in one, galbanum or castor in another, or musk, or sumbul, and the rest of these singular nervines. But none of these combinations can compete in convenience and efficacy with that invaluable salt, the valerianate of zinc. Many years before this substance was introduced, I had been in the habit of prescribing a well-known combination of oxide of zinc, extract of valerian, and extract of hyoscyamus, with a degree of benefit which had often far exceeded my expectations. And I remember the eager interest with which I first observed in one of the foreign journals the announcement of this new combination of zinc and valerianic acid. If I may venture on such a remark, I should say that, judging from the prescriptions which I have met with, this medicine is usually given in doses far too small. My own knowledge of the larger doses was, in the first instance accidental. For a lady, suffering a singular laryngeal

spasm after influenza, I had prescribed a grain of valerianate of zinc in a powder (as she was unable to swallow a pill), to be taken every three hours. Six grains had been directed to be distributed into six powders, but the dispenser had sent six powders, each containing six grains. In the morning I found that the powders had been taken with marvellous benefit, and no distress to the stomach. I need not say that this accidental lesson was not lost upon me, and that I have since prescribed the medicine in bolder doses than previously.

Iron may perhaps be classed next to zinc in value. Some practitioners would place it higher. When neurotic susceptibility is conjoined with poverty of colouring matter in the blood, its value can scarcely be over-praised. But even without this conjunction there are cases in which ferruginous preparations have great efficacy; but we are oftener checked in the use of this metal when we administer it in other diseases, by complaints of the pain or distress which it excites in the head, than by any other symptoms attendant upon its use. Still every practitioner must have remarked its signal utility in cases of headache with great debility, especially when the constitution has been worn down by previous disease. The carbonate has been used more frequently than any other form for the cure of strictly neuralgic headache. It is difficult to find a reason for the preference which many have given to this preparation, unless it be, that as it is very partially soluble, and is therefore given in large doses, it enters the system in very minute quantities at a time. Perhaps, as it is applied to so extensive a surface in the gradual travel of its large quantity through the tube, more may eventually enter the blood than when a small dose of a more soluble salt has been taken.

Of copper I have very little experience as a remedy for cephalalgia. I have used it in the form of ammoniacet, as in epilepsy, but with no very decided results. Were I pressed for a new agent, or a new combination in some very refractory case, I should try small doses of the sulphate of copper, in combination with quinine, as in Sir Henry Hallford's favourite combination for epilepsy.

Nickel was first brought before the notice of the profession by Dr. Simpson. He one day introduced me to a gentleman who had been a sufferer in an unusual degree, and for a long time from headache, and in whom sulphate of nickel had been of more avail than other remedies, but I did not learn what those other remedies had been. I have since then employed it in several cases, and I think always with some benefit; the dose has been a grain thrice daily.

It is highly probable that all the metals have more or less control over those new forms of neurotic life in which nervous diseases consist, and we may yet add some shafts to our quiver, tipped with selenium, cerium, and cadmium, to which Dr. Simpson has directed the attention of the profession.

When speaking of quinine, I ought to have remarked that beeberrine in large doses, has seemed to me to act in a manner very similar to that of quinine.

(To be continued.)

## ORIGINAL COMMUNICATIONS.

### ON THE INDUCTION OF PREMATURE LABOUR BEFORE THE SEVENTH MONTH OF PREGNANCY (a).

By ROBERT LEE, M.D. F.R.S.

Physician to the British Lying-in-Hospital, and Obstetric Physician to St. George's Hospital.

On the 7th January, 1812, a paper by Dr. Merriman was read to the Medical and Chirurgical Society, entitled, "Cases of Premature labour artificially induced in women with distorted Pelvis: to which are subjoined some Observations on this Method of Practice." This important practical communication was published in the third volume of the Transactions of this Society, upwards of forty years ago; but in the

(a) Read before the Royal Medical and Chirurgical Society in 1812.

thirty-two volumes which have since appeared, there is not contained the history of a single case in which premature labour was induced, though in these volumes the histories of ten cases of Cæsarean operation have been reported. As the safety, efficacy, and morality of the practice of inducing premature labour are still questioned by many foreign and English practitioners, I have thought the history of the following case, which has recently occurred, not unworthy of being presented to this Society, through whose influence Dr. Merriman was first enabled to bring the subject in the grave form it merited under the consideration of the whole Medical Profession.

On the 27th October, 1849, Mr. Booth, of Great Queen-street, Westminster, requested me to see Mrs. S., who had been in labour forty-eight hours, and whose pelvis was greatly distorted with malacosteon. After perforating the head, I succeeded in extracting it with the crotchet, after great exertions, continued for more than two hours. The patient recovered in the most favourable manner. Her lameness, which commenced four years before, gradually increased after this confinement. At the beginning of December, 1852, I was informed by Mr. Booth that this patient was in the fifth month of pregnancy, and I made an attempt to induce premature labour, but the os uteri was so high up and so small that the attempt to pass the probe-pointed stiletted catheter into the uterus was speedily abandoned, and it was determined to allow the pregnancy, about the existence of which even there was some doubt, to go on without interruption for another month. On the 6th January, 1853, I again saw the patient, and made a careful examination of the pelvis, which was found distorted in the highest possible degree, even more than the pelvis now placed upon the table of the Society. The tuberosities of the ischia were almost in contact, and the sacrum projecting forward so as to be not more than one inch distant from the bones of the pubis. The impression made upon my mind by this examination was, that I had never before encountered in practice so formidable a case of difficulty from distortion of the bones of the pelvis. It appeared highly probable if premature labour could not be induced, that the patient would either die undelivered or be subjected to the Cæsarean operation. I found some difficulty in passing the fore and middle finger of the left hand into the vagina, but after a time succeeded, and by pressing the anterior wall forward with the middle finger I succeeded at last in touching the anterior lip with my forefinger, and guided by this passed the point of the instrument through the os and cervix uteri into the cavity, and punctured the membranes. The liquor amnii immediately began to escape, and continued flowing till the morning of Friday, the 7th January, at 4 o'clock, when labour pains commenced. At 2 the os uteri was so much dilated, that the points of two fingers could be introduced, and the fact distinctly ascertained that the presentation was prenatural. At 7 p.m. the right arm was hanging out of the external parts, and the shoulder and thorax were forced down partially through the brim of the pelvis, and we were greatly pleased to find that the short diameter of the outlet was much increased by the tuberosities of the ischia having been pressed asunder. The operation of turning being considered wholly inadvisable and impracticable in this case, after carefully ascertaining the position of the fœtus, I resolved to eviscerate the fœtus, and afterwards with the crotchet fixed on the spine, as near as possible to the pelvis, to extract the nates and lower extremities. This was successfully done in a quarter of an hour, and in less than five minutes more the head was delivered without the employment of much force, and without the use of the perforator and crotchet. The patient recovered most favourably, and is still alive. The settled conviction left upon my mind by this case is, that a higher degree of distortion of the pelvis will never again be met with, and that if such a case should occur it would be possible to induce premature labour, and that it would be the duty of the practitioner to do so even before the sixth month of gestation.

Dr. Merriman was of opinion that the induction of premature labour by art "ought to be strictly confined to those melancholy cases of distorted pelvis, for which it was originally recommended," and the operation "should never," he says, "be undertaken, till seven complete months of utero-gestation have elapsed;" "that the practice should never be adopted till experience has decidedly proved that the mother is incapable of bearing a full-grown fœtus alive;" and that

"the operation ought not to be performed where the patient is labouring under any dangerous disease." These rules, laid down by Dr. Merriman forty years ago, "in order to guard against any abuse of this method of practice," may now, I believe, with safety and advantage, be greatly modified and extended.

It has been proved, by the results of extensive observation, that the induction of premature labour, which I regard as the most important improvement ever introduced into the practice of midwifery, is not only efficacious in all forms and degrees of distortion of the pelvis, but in cases where ovarian, uterine, and bony tumours obstruct delivery; in cicatrices of the vagina; malignant diseases of the os and cervix uteri; in organic diseases of the heart and lungs; in dropsy of the amnion, and general dropsy; in renal and vesical diseases; in cases where the death of the fœtus in utero repeatedly occurs from morbid alterations in the structure of the placenta, and other causes; in mania during pregnancy; and especially in cases where obstinate and incurable vomiting occurs in the early months of gestation.

ON THE

## TREATMENT OF SEROUS EFFUSION INTO THE PLEURA.

By HAMILTON ROE, M.D.

Senior Physician to the Brompton Hospital, and late Senior Physician to the Westminster Hospital.

THE difference of opinion which is known to prevail among the most eminent members of the Medical Profession, as to the best mode of treating several grave diseases, is productive of so much evil, that it ought, if possible, to be removed. It induces the belief that Medicine is a conjectural art merely, and not a fixed science; it weakens the confidence of the public in their Medical advisers, and is supposed to justify sensible men in giving heed to the dishonest boasting of empirics—that they are able to cure every disease.

That different remedies have been found efficacious in the treatment of the same disease, the high position of many of those who have advocated their employment, forbids us to doubt; for we cannot believe that those men could have either misstated, or been mistaken as to their effects; but the action of some of them is so opposite to that of others, that we can only understand how benefit could be derived from all of them, by supposing that such disease consists of varieties, which differ so much from each other as to require different remedies. We are all aware that many diseases have varieties, which are distinguished from each other by their constitutional as well as pathological peculiarities, and if a Medical author, instead of carefully describing the characteristics of the variety for which he has found a particular remedy useful, recommend that remedy for the treatment of the generic disease, those who employ it in other varieties for which it is not suitable, must find it useless, possibly injurious, and other remedies much more efficacious; and thus a difference of opinion is produced as to the best treatment of that disease. This difference of opinion, however, is more apparent than real; for, correctly speaking, it is not on the same but on different diseased states it is entertained; but it never can be removed, until a careful examination is made of all the varieties of such disease, giving a description of the characteristics of that for which each remedy has been found suitable. We are really in want of a nosological arrangement, in which distinction shall be made between all the forms of disease that do not admit of the same treatment, however they may resemble each other even in their pathological conditions. The same disease in different constitutions cannot be successfully treated by the same remedy: and therefore, a classification which groups together diseases merely because they are either similar in their nature, or seated in the same organ or structure, may afford us little or no assistance in the practice of our Profession. Early experience shows us how fallacious the conclusions may be which are drawn from statistical tables of the results of every kind of treatment of diseases which bear the same name, for the very same remedy appears, according to one observer, to have been successful, and according to another unsuccessful. And if these diseases have

varieties which require different remedial measures, the numerical results must vary according to the proportion which the number of those for whom any particular remedy is suitable, bear to the whole number of those to whom it is given.

Effusion of serum into the pleura is a disease respecting the treatment of which there is a considerable difference of opinion. Some Physicians advise mercurialization, and think it ought to be repeated from time to time till the fluid has been absorbed. Others recommend iodide of potassium and tonics, as iron combined with alteratives. Others, again, recommend tonics only; and a fourth class of Medical practitioners believe that the withdrawal of the fluid by tapping is very frequently the best mode of treatment.

The cause of this difference of opinion appears to be, that the disease in question has several varieties, for some of which each of the remedial measures just enumerated is the most appropriate; and that what had been found useful in one variety, has been declared to be useful in all. That this disease consists of varieties to be distinguished from each other by marked constitutional, as well as pathological differences, is well known to us all. The fluid found in the pleura is sometimes limpid and straw-coloured, with comparatively little albumen; at other times it is opaque, loaded with albumen, and contains flakes of coagulable lymph. These differences are not easily detected during life, and therefore cannot serve as the basis of a classification. But not so the constitutional peculiarities of those who are attacked by this disease, some of whom may be robust and vigorous, others feeble and depressed; these with the greater or lesser degree of intensity of the symptoms present, characterise varieties for which peculiar treatment is indicated.

Every one who has had many patients under his care is aware that fluid is effused into the pleura of strong robust persons, and into those of weak or enfeebled subjects; that in the former class it is effused much more rapidly, and is attended with much more marked symptoms than in the latter. Thus we have strongly marked symptoms of pleurisy with rapid effusion, constituting one variety; and obscurely marked, and often unperceived symptoms of pleurisy, with slowly effused fluid, constituting another. This latter variety also admits of subdivision according as the quantity of fluid in the pleura is great or small. Sometimes it fills, or nearly so, the whole cavity of the pleura, at other times it is very inconsiderable in amount, occupying only the lower third, or even less, of that cavity. The first variety I propose to consider is the effusion that takes place rapidly, and in considerable quantity, accompanied by strongly marked inflammatory symptoms.

When pleurisy attacks a robust and healthy person, there is generally more or less acute pain, and therefore the patient endeavours to keep the affected side motionless; there is, also, a sharp quick pulse, hot skin, and all the symptoms of inflammatory fever. The fluid is secreted so rapidly that in a short time a great portion of the chest sounds perfectly dull on percussion, ægophony is distinctly heard, and the breathing becomes much oppressed: in a little more time the whole chest sounds dull, ægophony is no longer heard, and suffocation seems imminent. For such cases, which in London are of rare occurrence, bleeding from the arm, sometimes more than once if the fever be not sufficiently reduced by it, followed by calomel and opium, with sedatives, administered so as to produce salivation in the shortest possible time, are remedial measures which are generally effectual, not only in curing the inflammation, but in removing the fluid. There is no difference of opinion, that I am aware of, as to the treatment of this form of affection, and therefore I will give but one instance of it:—

*Case 1.*—Mrs. E. Loudon, aged 28, a strong-built, healthy-looking woman, a nurse in the Westminster Hospital, was seized on Friday, April, 1832, with sharp pain of the left side, which was greatly increased by making a full inspiration, short cough, difficulty of breathing, considerable heat of skin, quickness of pulse, and all the other symptoms of sharp inflammatory fever. The lower part of that side was dull on percussion, and the breathing was indistinctly heard. Twenty ounces of blood were taken from the arm, two grains of calomel and half a grain of opium were given every four hours. Next day the breathing was more difficult, and she could not lie down. The dullness extended up to the clavicle, and no ægophony could be heard; the respiration was bronchial, and the heat of skin and symptoms of fever continued. She was

bled again to sixteen ounces, one grain of digitalis, and a quarter grain of tartarised antimony, were added to the pills already ordered of calomel and opium, and they were directed to be given every two hours until salivation came on. Finding the fluid increasing so rapidly and the symptoms so urgent, I appointed next day at 2 o'clock for tapping her chest, desiring that I should be sent for in the interim if she became worse. But when we arrived, salivation had taken place, the fever had subsided, ægophony could be heard, the dullness did not extend nearly so high on the chest as it had done the day before, and the urgent necessity for tapping no longer existed. The same pills were continued every eight hours for a few days longer, and in less than fourteen days, all symptoms of fluid had disappeared, and the woman was convalescent, and soon resumed her duties.

The second variety is characterised by a large quantity of fluid, slowly and often imperceptibly effused into the pleura, without symptoms of inflammation sufficiently great to attract attention. In such cases, the great object is to remove the fluid, and to prevent it from being again secreted, the symptoms of inflammation requiring little attention. For the removal of the fluid two remedial measures are relied upon, mercurialization and paracentesis thoracis, and each of them has its advocates. Those who advise the former, argue that it will not only remove the fluid, but by subduing the inflammation on which it depends will prevent it from returning, and thus render paracentesis unnecessary, and that this operation should never be performed till the breathing becomes depressed. Those who advise the latter mode of treatment maintain that when the pleura is much distended with fluid, salivation will not effect the removal of it; that it often fails to do so when the quantity of fluid is much less; that even in those cases where it does effect its removal, it takes so long a time to do so that the lung becomes compressed by the fluid; and even if it should ultimately effect a cure, it must be by the agglutination of the pleural and costal membranes, the obliteration of the pleural cavity, and the falling in of the thoracic parietes, and therefore deformity must be produced; further, that the administration of mercury to persons of weak constitutions is always dangerous and sometimes fatal; whereas, tapping the chest is a perfectly safe, effectual, and almost painless way of evacuating the fluid. We now know little from personal experience of the fearful ravages which mercury made in the last century, the deformities it occasioned, and the irremediable injury it did to the human constitution; but the cranial and other bones perforated with holes, as if worm-eaten, the skulls from which half of the face had decayed away, and the other illustrations of the injurious action of mercury which our museums furnish, show us that it is a dangerous remedy, and afford such proofs of the effects it sometimes produces, as to warn us against the unnecessary or incautious use of that medicine, and to induce us to prefer any other which, with less risk of doing mischief, promised to effect the same amount of good. But the objection to the use of mercury pushed to salivation in such cases is not merely that it is a dangerous remedy, but also, as I have said, that it is one which often fails in effecting the removal of the fluid. Every one must have observed that salivation does not promote the absorption of serum from any cavity which is much distended by it; it cannot, therefore, be expected to do so from the pleura. That it will sometimes fail of doing so, even when the cavity is not filled, is shown by the following case:—

*Case 2.*—Mr. C., aged 26, a surgeon practising in the country, not many miles from London, was seized early in the spring of 1846 with symptoms of acute pleurisy of the left side, after having been in a cold bath. He was of middle size, not slightly made, but pallid, and his circulation was feeble. His brother had died of consumption, and he himself had had hæmoptysis some year or two before. He consulted Mr. Bullock of Great Cumberland-street, who was his friend, and by his advice he was bled twice from the arm, had leeches applied to the chest, and took calomel and opium every four hours till he was salivated. Under this treatment he recovered sufficiently to attend to his business; but he looked pallid and delicate. Three or four months afterwards, he began to feel pain in the side formerly affected: a short cough and some difficulty of breathing. On examination, fluid was found in the pleura. By the advice of a Physician, whose pupil he had formerly been, he again took mercury, and was salivated, but the fluid was not removed. In July it reached the

posterior and inferior angle of the scapula. In that month I saw him, in consultation with Mr. Phillips and Mr. Bullock, and advised tapping. Four pints of clear straw-coloured fluid were drawn off by Mr. Phillips, and he was again advised to take mercury, contrary to my wish, by the physician who first attended him. In about six weeks the fluid had again accumulated in his chest, and at his own desire he was again tapped, and was again salivated. He was then so much debilitated that he was obliged to keep his room when the weather became cold. Every six or seven weeks the fluid reaccumulated in his chest, and was removed by tapping, after which mercury was given him. He lingered about eighteen months from the date of his first attack, and during this period he was tapped about seven times, and was salivated four or five; and he died at last of acute pleurisy, complicated, as I believe, with phthisis. Here was one case in which salivation neither removed the fluid, nor prevented it from being re-secreted; and in which it allowed acute pleurisy to supervene in a constitution debilitated by its use. This one case shows that in persons whose constitutions are similar to this gentleman's, we cannot feel confident that mercury will effect the removal of serum effused into the chest, and that there is much reason to fear that its exhibition to any extent will produce constitutional injury. On the other hand, it is objected to tapping, that it is attended with some degree of risk from the admission of air, and that, inasmuch as it only removes the fluid, and does not remove the condition of pleura which gives rise to the secretion, it cannot be an effectual remedy. I should be occupying the time of the Society unprofitably if I were to reply to the first objection otherwise than by appealing to facts. What cases are there upon record in which the admission of air, during the operation, produced any serious, even temporary inconvenience? I am not acquainted with any. In the paper which I read before the Royal Medico-Chirurgical Society in the year 1844, I stated, that in all the cases which had fallen under my observation, and they were many, air had entered, and in some of them in considerable quantity, and in not one had it produced any permanently evil effect; there is in reality no foundation but theory for this objection. To the second objection I reply by asking the question, Does the fluid always reaccumulate when it has been withdrawn by tapping? The cases which I recorded in 1844, and those which I have had under treatment since that year, prove that it does not; it has reaccumulated in some cases, certainly, but I believe these were cases in which either the inflammation was not subdued previously to the performance of the operation, or in which the operation had been too long delayed. If the operation be deferred, as it is advised to be, till great difficulty of breathing imperatively calls for its performance, it is almost certain that fluid will be again secreted, for it is clear that the lungs have then been so altered in their structure as to have lost the power of expanding as the fluid is being withdrawn, and that air must enter to supply its place. Under such circumstances experience has taught us that the resection soon commences. A lung cannot remain many weeks compressed by fluid without becoming carnified, and thus rendered incapable of ever regaining its natural vesicular and elastic structure. Tapping to be a remedy must therefore be performed before this change has taken place in the lung; indeed, if it be not, it will be injurious rather than useful. The earlier it is performed, the less likely is the disease to return, provided no inflammation be going on in the pleura. Tapping is the speediest way of removing the fluid; it causes less suffering, and inflicts much less injury upon the constitution than mercury; it is free from danger also; on all these grounds I prefer tapping for this form of effusion to salivation. Even granting for argument's sake that the fluid may always be removed by salivation, a more than doubtful assertion, the anxiety which is manifested by many of my professional brethren to prove that tapping is unnecessary, greatly surprises me, as if it were the most formidable remedy to which they could have recourse; for were I myself the subject of this form of pleuritic effusion, I should infinitely prefer its being performed upon me to being submitted to the pain and protracted suffering of repeated salivation, and the risk of the formidable consequences it sometimes produces. Mercury, largely exhibited to persons of weak constitutions, not unfrequently develops phthisis; and no stronger proof of a weak constitution is needed than the slow and unnoticed effusion of fluid into the pleura. The certainty of being able to remove the fluid by tapping, the absence of all real danger from the

operation, the little probability of fluid reaccumulating after it has thus been drawn off (as proved by the recorded cases), and the urgent necessity of speedily relieving the lung from a degree of pressure, which experience has proved will in no long time effectually prevent the lung from ever recovering its original elasticity, are the strong recommendations of paracentesis. On the other hand, experience has shown that salivation is not certain of effecting its object, and that in debilitated subjects it is a much more dangerous remedy. Another very strong argument in favour of tapping is furnished to us by the efforts so frequently made by nature to rid herself of fluid which has remained too long in the chest, by making an opening in one of the intercostal spaces in the lower part of the affected side, through which the fluid may be discharged. Many examples of this kind are daily met with in practice, and one is furnished by a case which I am now about to lay before the Society.

*Case 3.*—On the 14th of March, 1854, I was requested to meet Messrs. Evans, of Hertford, in consultation on the case of a gentleman, aged 19, a student of Haylebury College, who was suffering from fluid in his chest. I found him in bed, looking pallid and very feeble; his breathing short and accelerated, but not difficult or laborious; he could not, however, utter many words without making an inspiration; his left side was rounded and motionless; his pulse was 120, small and weak.—Mr. Evans said it was usually 110; his skin was cool and perspiring; tongue white and coated. His appetite was bad, and his sleep was disturbed. When he sat up, the left side of his chest measured half an inch more than the right; it sounded very dull on percussion, and no respiratory sound was audible in it, either anteriorly or laterally, from the clavicle to the margin of the false ribs; posteriorly, also, it was very dull, but less so in its upper than its lower half, and respiration could be heard feebly in the superior part of it; but it was not tubular or bronchial. Egophony could not be detected. There was no bulging of the intercostal spaces, and the heart was felt beating to the right of the sternum. To make the diagnosis certain, a small grooved needle was next passed into the pleura in the fifth intercostal space, and between the edges of the pectoralis major and latissimus dorsi muscles, where we had previously ascertained no respiration could be heard, and clear straw-coloured serum made its appearance in the groove. This placed the nature of the case beyond doubt. He had no predisposition to phthisis or any other malady. When an infant, he had had measles and whooping-cough. Six years ago he had had scarlet fever severely; but he recovered from it perfectly, and enjoyed good health until within the last three weeks, during which he had suffered from flatulence and uneasiness about his left side, supposed to arise from indigestion; but he had no difficulty of breathing until within the last week. He noticed, however, that he could not run as well as usual, owing, as he thought, to his not being in good training. He now complained chiefly of slight cough, great debility, and nightly perspirations. On being closely questioned, he said that about January last he remembered having pain in his side, which he thought was produced by cramp; but it did not prevent him from riding on horseback, skating, and taking other active exercise. The question we had to consider was, how should this affection be treated? Two remedies suggested themselves, mercurialization and tapping. The former had the sanction of men well thought of by the Medical profession; but I objected to its being employed, on the ground that its acknowledged efficacy in those effusions which were caused by acute pleurisy did not warrant our believing that it would cure one of this sort, resulting either from latent pleurisy or some altered condition of the blood; that a long-continued salivation would be required to promote the absorption of so large a quantity of fluid as was contained in this gentleman's chest; and, after all, it was by no means certain that that would effect it; that it was not probable that effusion, to such an extent as to fill the pleura and displace the heart, could have taken place in the short time which had elapsed since his health began to fail, from any other cause than acute pleurisy, which there was no evidence of his having had; that it was far more probable that effusion commenced in January, increased very slowly at first, and more rapidly of late, as his health gave way; that if it were allowed to remain much longer in the chest, a risk would be incurred of having the lungs cramped by compression; that the slowness with which this disease had come on indicated a

state of constitution that strongly contraindicated the use of mercury, and that the injury likely to be done by its administration was almost certain, whereas the benefit was uncertain. That, on the other hand, tapping was a remedy which I had never known to do injury; that the pain it gave was trifling and the relief immediate; that the respite it would give from suffering would allow time for recruiting health enough to bear up against the effects of medicines; and that after the fluid had been removed mercury might be given (if it appeared desirable), to prevent the recurrence of the effusion, with far more hope of success than could be entertained in giving it now to effect its removal; for these reasons I advised tapping.

(To be continued.)

## ON THE THERAPEUTICAL ACTION OF THE CONSTANT GALVANIC CURRENT.

By Dr. ROBT. REMAK, of Berlin.

AFTER the discovery of the voltaic pile (1800), many experiments were made with a view to the application of the galvanic current, as a means of treatment in diseases of the nerves and muscles. Stimulated by the admonitions of Alexander Humboldt, Loder of Jena and Grassengieser of Berlin were amongst the first to treat various paralytic affections of the limbs and sensorial nerves in this manner (1801). The opinion at that time being, that not the continued action of the current, but the shocks produced by the interruption of the current, are the best means of exciting the normal action of the nerves and muscles. These trials could not result in success, because, as my researches have now proved, such shocks can in very few cases be advantageously employed. Thus for many years the electrical machine formed the only means of producing and applying electricity to the above-named diseased conditions; and the opinion was generally adopted by Physicians, that it signified little from what source electricity for Medical purposes was produced.

Although the discoveries of Becquerel and Wollaston (1820-30) supplied the means of producing a constant and equable galvanic or electric current, Physicians did not avail themselves of these improvements, but preferred using the magneto-electrical and electro-magnetic machines which were constructed after the discovery of the current of induction, made about the same time as Becquerel and Wollaston's, by Oersted and Faraday. In experimenting with these instruments, the fact was overlooked that the current of induction cannot be applied to the living body without producing shocks (i. e. spasmodic contractions of the muscles), and that these shocks have a weakening effect. At last the chief consideration came to be, the easiest method of procuring electricity for Medical purposes. So at last the magneto-electric machine (of Saxton, Stoecher, etc.) gave place to the self-acting electro-magnetic (galvano-magnetic) machine of Faraday, which was recommended by Duchenne, of Paris, and was much approved of in France and Germany. In the work of that Physician (a) it was stated that muscles are made to contract most readily by the current of induction, if certain points on their surface are touched by the electrodes. Having been occupied for many years with physiological researches upon muscular contraction (b), I was not a little curious to know the nature of these mystical points; and, on directing my attention to this subject, I soon found that they corresponded with the points of entrance of the muscular nerves, and that the degree of contraction of a muscle was proportionate exactly to the number of motory nerve-fibres embraced by the current at its point of application.

I stated the result of these physiological investigations in a small pamphlet, published in 1856, and drew attention to their value in a practical point of view. It seemed to me quite obvious that, for the successful therapeutical application of electricity, a better and more extensive physiological basis was required than was afforded by this one fact; so, in continuing my researches on the subject, I was led to examine the effect of the constant galvanic current (as it is produced

by the elements of Daniell, Grove, or Bunsen) on the muscles and nerves of a healthy man. The results of these further observations I noticed in an appendix to the second edition of the pamphlet last quoted, also in a note sent to the Academy of Paris. (c) After having continued such researches, made upon my own person, and upon many healthy men, for about six months, I was induced, in July, 1856, to apply the constant current as a means of treatment of contractions of muscles, in cases of hemiplegia from cerebral apoplexy. The most important result of this application was the fact, that the continued current applied for a few minutes to a contracted muscle had the effect of immediately relaxing it to a certain extent, and rendering it amenable to the influence of volition. (d)

After repeating these trials upon 200 cases of different kinds of nervous diseases, I reported as the result of my further experience that the continued application of the constant current to the nerves and muscles in rheumatism, paralysis, atrophy, neuralgic and spasmodic diseases, had in my hands proved of much greater service in a curative point of view, than any other application of electricity had hitherto done (e). I gave my results in a memoir which I read before the Academy of Sciences at Paris, in *séance* Sept. 22, 1856 (f); and on the 29th of the same month I made some experiments before M. Rayer, who was representative of a commission appointed by the academy for the purpose (g); and on the following day repeated them before a number of Physicians and Naturalists.

From that date to the present, I have spent all my time in continuing these researches, and in endeavouring to develop the methods of application of the constant current. In the Society of Medical Science of Berlin, I stated (Jan. 19, 1857) that the diseases in which the constant galvanic current is of service, are—1. Rheumatism, acute and chronic. 2. Cerebral hemiplegias. 3. Paraplegias. 4. Atrophy of muscles. 5. Chorea. 6. Stammering. 7. Trembling of limbs. 8. Cramps of writers; and I have supported my assertions by presenting cases of these descriptions, which were either cured or improved by this mode of treatment (h). My subsequent publications upon the subject were directed principally to the treatment of atrophy (i) and paralytic diseases (k). This was accounted for by the fact that certain physiological views, dating from the time of Volta, Mariamni and Nobili, gave rise to the opinion that the continued action of the current had only a relaxing or weakening effect, and could do good only in spasmodic diseases (l). I have refuted this idea by showing that the continued current applied in a certain manner, is of use in many cases of paralysis in which the interrupted current of induction is even productive of harm (m).

One of the most curious results of my researches made during the last year is the observation, that the constant galvanic current, by dilating the blood-vessels, and by promoting absorption of exudations can be used with good effect in certain inflammations in which the other antiphlogistic and resorbent remedies are insufficient (n). There is no doubt that the electrolytical power of the constant current (discovered by Nicholson and Carlisle, 1800) is a powerful means of producing these effects. I have already seen most convincing and gratifying proofs of this fact, not only in rheumatic and traumatic inflammations of joints, but also in the inflammatory states of the spinal marrow which sometimes

precede atrophy of this organ (?) (o). It may readily be supposed that the mode of applying the current must be very different in order to produce the various actions I have hitherto distinguished—viz. 1st. The catalytic (i.e. electrolytic and antiphlogistic); 2nd. The antiparalytic; 3rd. The antispasmodic. But for information on this subject, I am obliged for the present to refer to my various publications.

In Germany my experiments have not yet been repeated; but in France, after my visit in September, 1856, some Physicians made some trials upon the subject, and, as I am now informed, these were not unattended with success. In England I do not know if anything has been done in this way, but it is the object of this short paper to direct the attention of my English colleagues to this discovery (as I dare to name the methodic application of continued galvanic currents to diseased conditions), and I would feel satisfied if I thought that the methods described by me in a work I am about to publish, would in any way assist them to the successful practice of their art.

Finally, I think it my duty to state distinctly, that all my experiments upon 700 patients have been made only with the constant galvanic current (of Daniell, Grove, and Bunsen), and that there is reason to doubt if these results could have been obtained by the use of other elements less constant.

### PRACTICE OF MEDICINE AND SURGERY.

#### HOSPITAL NOTES.

##### NEW OPERATION FOR ARTIFICIAL PUPIL.

Mr. Critchett has recently adopted at the Moorfields Ophthalmic Hospital a mode of operation, where it is wished to displace the pupil, which is, we believe, novel. Instead of drawing out and snipping off a portion of iris, he draws it out and secures it by a fine ligature from slipping back. It may, perhaps, at the first mention seem that the result must be nearly the same as if the scissors were used, since the portion included in the ligature will slough away. There is, however, another point in Mr. Critchett's proposal which indeed constitutes its main feature. It has long been an aim with Ophthalmic Surgeons to discover some mode of operating by which the natural pupil should be simply displaced to the elected position without laceration of its margin. This was the end sought to be obtained by the ingenious suggestion of a surgeon of Nantes, to remove a small portion of cornea near its circumference, and then allow the iris to bulge and become adherent to the cicatrix. This latter mode of operating has been frequently adopted of late by Mr. Bowman and other English Surgeons, and we have seen some excellent pupils obtained by it. It is of course the substance of the iris near its circumference which bulges into the wound, not its pupillary edge. Now, Mr. Critchett aims to exactly imitate this process, with the advantages that no portion of the cornea is excised, and that the result is much more certain. Having made an incision close to the corneal edge sufficient to admit of Leur's forceps, the iris is seized just within the opening (that is, very near to its attached border), and is gently drawn out until enough is prolapsed to allow of the application of the ligature. The ligature prevents all chance of the return of the iris which might otherwise follow. Mr. Critchett has now performed it in four instances, and last Friday Mr. Bowman also adopted it in a case under his care. It is, of course, best adapted for cases of leucoma, &c. where the iris itself is not diseased. If the pupil have strong adhesions, one or other of the numerous older methods would be better suited.

##### ACCIDENTAL IMPALING ON THE HANDLE OF A PARASOL.

A few days ago, a lady was carried into St. Thomas's Hospital from the London-bridge railway-station, with the state-

ment that she had fallen, and been taken up insensible. She died whilst being carried up the steps, and within ten minutes of her fall. An omnibus driver, who had witnessed the occurrence, stated that whilst walking down the slope of flags from the station, she had appeared to catch her foot or tread upon her dress, and that she then fell heavily forwards. At first, therefore, the conjecture was that either apoplexy or cardiac disease, or possibly a fracture of the base of the skull, had been the cause of death. It was soon found, however, that there was much blood on the upper part of her dress, and on further search a small penetrating wound was discovered, which passed through her mantle and other articles of apparel, and entered the thorax immediately beneath the left clavicle. The cut in the cloth mantle had sharp edges, as if done by a pointed instrument, but the linen articles were torn rather than incised. The wound in the skin was very much what might have been expected from a dagger. The conclusion which now suggested itself was, the case must be one of murder by the stiletto. At a subsequent period, however, a gentleman who had been on the spot, and who had assisted in lifting her up, produced a parasol which he said he had found at the time entangled in her dress, and had withdrawn immediately, without, however, being in the least aware that he was drawing it out of her body. The parasol handle had been broken off, leaving a sharp splintered end, the condition of which left no room for doubt, but that it had been the cause of the fatal injury. The autopsy showed a penetrating wound of the thoracic parietes and of the apex of the left lung, the instrument having then passed obliquely upwards into the root of the neck. The pleural cavity contained a large quantity of blood.

##### USE OF CHLOROFORM IN SOUNDING FOR STONE.

It is always a mortifying occurrence to a Surgeon to miss the finding of a stone in the bladder, and leave the discovery to be made by some one else. We not unfrequently have cases brought under our notice in which a patient submitted to lithotomy at one Hospital, gives the statement that he has been previously sounded at some other institution, and told that he had no stone. These mistakes are especially liable to occur in young subjects, and when the stone is small and light. We believe, however, that the neglect to give chloroform, and to inject the bladder before the use of the sound, is fairly chargeable with many of them, and that the Profession would gain in character, and individuals often be saved much annoyance if these precautions were never omitted. To sound a squalling, struggling child, who in all probability has emptied his bladder at the sight of the instrument, is no easy affair, and not by any means likely to afford trustworthy conclusions. On the other hand, children bear chloroform remarkably well, and we are at a loss to conceive that any inconvenience would result from its habitual employment under such circumstances.

#### THE PROVINCIAL

### PRACTICE OF MEDICINE AND SURGERY.

#### STATISTICAL REPORT OF THE PRINCIPAL OPERATIONS PERFORMED DURING THE YEAR 1857.

(Continued from p. 451.)

THE subjoined Report comprises the following Hospitals:—Addenbrooke's (Cambridge), the Bristol General, the Cheltenham General, the Cumberland (Carlisle), the Derby General, the Dorset County (Dorchester), the Dundee Royal Infirmary, the Glasgow Royal, the Gloucester, the Hull, the Leeds, the Leicester General, the Liverpool Royal, the Liverpool Southern and Toxteth, the Queen's, Birmingham, the Sheffield General, the South Staffordshire (Wolverhampton), the Staffordshire General (Stafford), the Sussex County (Brighton), the West Norfolk and Lynn (Lynn), the York County.

##### EXCISIONS OF BONES AND JOINTS.

Case 1.—The Bradford: Mr. Mead.—A fairly healthy lad, aged 19. Excision of the knee-joint on account of chronic

o) Ueber die Behandlung der Tabes dorsalis mit const. galv. Strömen, in die Protocolle der Sitzung der Hufelandschen gesellschaft, v. 26 März. 1858), Allg. Med. Central Zeitung, 1858, No. 29.

synovial disease. Death from pyæmia on the thirteenth day. *Case 2.*—The Bradford: Mr. Mead.—A man, aged 47, in fair health. Excision of the scapula and head of humerus on account of malignant disease. There was considerable hæmorrhage during the operation. Death from exhaustion two hours afterwards. *Case 3.*—The Leeds: Mr. Smith.—A girl, aged 20, of healthy appearance, for two years the subject of diseased elbow-joint. Several fistulous openings existed. Excision of the entire joint in the usual manner. Recovery. In this case cicatrization was complete within a month. *Case 4.*—The Liverpool: Mr. Bickersteth.—A strumous boy, aged 10, the subject of diseased elbow-joint. There were three or four sinuses around the joint, and the bones were extensively diseased. A free excision was performed, the H-incision being adopted. Recovered well. *Case 5.*—The Liverpool: Mr. Long.—A man, aged 25, in poor health. The subject of disease of the shoulder-joint. The joint was stiff, and several sinuses both in front and behind led into it. After some preparatory treatment, excision of the head of the humerus was performed. In the attempt to displace the head of the bone from the glenoid cavity, the shaft broke through at the insertion of the deltoid. The head of the humerus was found to be firmly ankylosed to the glenoid cavity, and some little trouble was required for its removal. The man did well. The fractured bone united firmly, and a fair amount of motion in the false joint was retained. Two sinuses still existed at the time that he was sent into the country for change of air. *Case 6.*—The Liverpool: Mr. Bickersteth.—A healthy lad, aged 12, the subject of disease of the elbow-joint. Excision of the joint by the H-shaped incision. Recovery, with a fair amount of motion. *Case 7.*—The Royal Berkshire Hospital. A cachectic woman, aged 29, the subject of diseased shoulder-joint. Her strength failing, excision was determined on. The operation was performed in the usual manner; the head of the humerus was found extensively carious. The glenoid cavity was gouged. She suffered for some days from the shock of the operation, but afterwards did well. She was the subject of enlargement of the liver, and there was also a suspicion of lung disease. She left the Hospital on April 24, the operation having been performed on March 12. The wound never ancturely healed; death took place early in June. No autopsy. *Case 8.*—The Royal Berks.—A young woman, aged 23, in good health, but the subject of disease of the hip-joint of two years' standing. The disease had been acute only for three months, and was rapidly undermining her health. A single sinus in the thigh discharged profusely. After various measures of treatment, excision of the head of the femur was performed four months after her admission. The acetabulum was found much diseased and required free gouging. A finger could be passed through it into the cavity of the pelvis. She recovered well from the shock of the operation, but no reparative action was set up, and death took place on the fourth day. *Case 9.*—The Leeds: Mr. Teale.—A lad, aged 19. Excision of the elbow-joint, on account of chronic disease. The soft parts were much infiltrated and swollen, and healing consequently progressed slowly. Passive motion was commenced about a month after the operation. Recovery. *Case 10.*—Addenbrooke's: Mr. Humphry.—A healthy man, aged 31, for three years the subject of diseased ankle-joint. A complete excision was performed, the upper surface of the astragalus, and the lower end of the tibia, with both malleoli, being sawn away. No ill symptoms followed. Seven months afterwards the parts had healed, but the leg was still weak. *Case 11.*—Addenbrooke's: Mr. Humphry.—A girl, aged 5, in delicate health, the subject of acute suppuration of the knee-joint, following old-standing disease of the patella. Excision of the joint. Diarrhœa was set up the next day, and continued to the time of death; death occurred on the twenty-second day, having been preceded by swelling of several of the joints. No autopsy was allowed. *Case 12.*—Addenbrooke's: Mr. Humphry.—A healthy labourer, aged 25, the subject of diseased knee-joint, following the kick of a horse. Excision of the joint. At first the case progressed very well, but subsequently abscesses formed about the bones. Seven months afterwards there were still some discharging sinuses, but the bones had firmly united. *Case 13.*—Addenbrooke's: Mr. Humphry.—A pale, unhealthy-looking man, aged 25, with disease of the knee-joint of three years' standing. Excision of the joint was performed. In the operation commencing ulceration of the cartilages was found, and numerous small polypoid growths from the synovial mem-

brane; the latter were all removed. Erysipelas of the leg followed, and abscesses formed about the seat of the operation. Amputation through the thigh three months after the excision. Recovery. *Case 14.*—Addenbrooke's: Mr. Humphry.—A delicate lad, aged 10, for a year the subject of diseased knee-joint. There was an abscess in the ham, communicating with the joint. Excision of the joint. The edges of the wound separated, exposing a large suppurating surface. His health giving way, amputation through the thigh was performed three months after the excision. He recovered well. *Case 15.*—The Derby: Mr. Fearn.—A feeble lad, aged 18, the subject of diseased wrist. Excision of the diseased articular surfaces. Some sinuses still existed at the time he was made an out-patient. *Case 16.*—The Derby: Mr. Fearn.—A delicate girl, aged 16, the subject of disease of the elbow-joint. Excision of the joint. The disease extended, and amputation through the arm was performed a month afterwards. She recovered well. *Case 17.*—The Liverpool: Mr. Long.—A healthy-looking lad, aged 16, the subject of diseased elbow-joint, resulting from a blow a year ago. The actual cautery had been applied with marked benefit, but the disease still existed. The H-shaped incision was practised, and the ends of the bone removed. He made an excellent recovery, and in less than three weeks could put his hand to his mouth; and in another three weeks could flex and extend the forearm quite freely. *Case 18.*—The Liverpool: Mr. Bickersteth.—A strumous lad, aged 18, the subject of old-standing disease of the elbow-joint. There were three or four sinuses which communicated with the joint. The H-incision was practised, and the ends of the bone removed. The boy did well, and was discharged in much-improved health, and with fair motion in the elbow. *Case 19.*—The Liverpool: Mr. Bickersteth.—A feeble woman, aged 56, the subject of diseased elbow-joint. Excision of the articulation. The parts had nearly healed, when the patient's health failing, her friends removed her from the Hospital. She shortly afterwards died. *Case 20.*—The North Staffordshire: Mr. Ball.—A girl, aged 12. Excision of the elbow-joint. Recovery, with good motion in the joint. *Case 21.*—The Staffordshire General: Dr. Masfen.—A healthy man, aged 37, the subject of diseased knee-joint. Excision of the joint, the patella being left. Death from exhaustion on the twenty-first day.

SATURDAY, MAY 8.

## MARRIAGES OF CONSANGUINITY AND THEIR RESULTS.

THE fact that intermarriage among blood relations is attended with the risk of unhealthy progeny, is one which the common observation and common sense of mankind have almost universally recorded. In this country, and possibly in all countries, the rudest of the people recognise this occurrence, and point it out as one which should not exist. Yet such is the perversity of minds—such the urgency of that principle which recognises present or temporary benefits, in opposition to disadvantages in prospect which may never happen in the course of the accidental future—that the common knowledge and assent to which we have made reference

are allowed to stand but for little in the way of the mischief foreshadowed. Self-interest, in one or other of its forms, predominates, and perpetuates an evil which tells not on the perpetrators, but on a race proceeding from them, having as yet no existing identity in time or matter.

Of all classes of the community, none know so well the nature of the evil now being discussed, as the Medical fraternity. To the Medical man the evils of intermarriage are the repeated confirmations of his daily experience. Seeking for evidence on which to make a sound diagnosis, he gathers all the information he can in reference to relationships and family ailments, and uses such information to an advantage which none but himself can comprehend. Yet, here, perversity again manifests itself in opposition to even scientific knowledge.

"Physician, heal thyself," is a proverb which has been oftener said than done. We want now, however, to see it done as well as said, and we therefore call professional attention to the subject of intermarriage, with the hope that a more perfect understanding of the importance of the question may be arrived at, and that our lecturers may see the propriety of teaching a great hygienic lesson by example as well as precept.

But little sound statistical information has as yet been collected to guide us towards correct conclusions on the matter in hand. This is from no deficiency of fact, but from deficiency of industry and definite observation. We are now, it is true, emerging from this state of inaction, and a few years will doubtless bring forth numerous labourers in the wide field of research which now lies open.

It is due to our American brethren to intimate, that in the re-opening of this engrossing topic they have taken the initiative. Our attention has been specially directed to a very able production in a late number of the *North American Medico-Chirurgical Review*, by Dr. Bemiss, of Louisville, some points of which are of singular value. Dr. Bemiss for the first time gives us statistical data as the basis of his argument.

The number of marriages of consanguinity, the histories of which were collected by Dr. Bemiss, are 34. Of this number 28 were of the third degree of the civil law, or between first cousins, and 6 were of the fourth degree, or second cousins. Of the total number of marriages, 27 were fruitful, and 7 sterile. The 27 fruitful marriages produced 191 children. In only 13 of these unions was the sex of the offspring reported, giving 49 males to 42 females—a proper proportion, by the way, as regards the division of sex. Of the 28 marriages of the third degree of relationship, first cousins, 23 were fruitful, and 5 sterile. Of the 6 marriages in the fourth degree, 4 were fruitful, and 2 sterile. In both these latter instances of sterility the female was the product of a marriage of consanguinity. The relative proportion of children to the total number of marriages was 1 to 5.6. The average fecundity to each fruitful union was 7, and a slight excess. The average births to each fecund marriage in the third degree of kinship was 6.87 nearly. The average number of births in the fruitful unions of the fourth degree was 8½.

Having so far marshaled his facts, Dr. Bemiss narrates the condition of the children thus propagated.

Of the 192 children born, 58 perished in early life. In 24 of the 58 deaths, the causes are stated as follows:—Of consumption, 16; of spasmodic affections, 8; of hydrocephalus, 1. Of the 134 who arrived at maturity, 46 are reported as healthy; 32 are set down as deteriorated, but without absolute indications of disease; and 9 are returned without any statement as to health or condition. The remaining 47 all possess such abnormalities as render them the subjects of particular observation. These are classed as follows:—23 are scrofulous, 4 are epileptics, 2 are insane, 2 are mutes, 4 are idiots, 2 are blind, 2 are deformed, 5 are albinos, 6 have defective vision, and 1 has chorea.

While in point of fecundity these marriages present nothing very unusual, they exhibit comparatively, as Dr. Bemiss thinks, results more than usually favourable to the offspring. In support of this opinion, he quotes a report on idiocy by Dr. Howe, in which that observer has narrated the history of 17 marriages of blood-relations. These 17 marriages gave birth to 95 children, of whom 44 were idiots, 12 scrofulous and puny, 1 deaf, 1 dwarf—58 in all of low health and imperfect, and only 37 of even tolerable health.

To define still more clearly the absolute influence of the blood-tie on the condition of the offspring, Dr. Bemiss has tabulated his results in the following manner. He divides the productive marriages in his report into three classes:—1. Those where the husband and wife are relations of the fourth degree, or second cousins. 2. Those of the third degree, or first cousins. 3. Those nearer than the third degree, viz. double cousins. The table, so constructed, stands thus:—

Degree.	No. of Marriages.	No. of Children.	Died.	Diseased.	Deteriorated.	Healthy.	Unknown.
4th degree.....	4	34	8	6	10	10	
3 " .....	19	130	37	31	17	36	9
2½ " .....	4	27	13	5	6	3	

The results of this table are sufficiently striking, and as far as they extend are conclusive in favour of the supposition that the mischiefs arising from marriages of consanguinity increase under certain peculiar circumstances in proportion as the ties of relationship grow closer.

We have thus in brief sketched out such data as are at present before the Profession on the question of intermarriage and its results. How this all-important matter may be more fully traced out involves considerations which our space this week does not permit us to discuss.

## THE WEEK.

Dr. Robert Law, one of the Physicians in ordinary to the Lord-Lieutenant of Ireland, has been appointed Visiting Physician to the Central Criminal Lunatic Asylum at Dundrum, in the room of the late lamented Dr. Harrison. Dr. Law's high character and distinguished professional reputation render this a most unexceptionable appointment. The Professorship of Anatomy in the University cannot be filled up for some time, three months' notice of the election in the Dublin and London Gazettes being required by Act of Parliament.

The last quarterly return of the marriages, births, and deaths in England presents an unfavourable aspect. "The marriages of the year 1857 and of the last quarter of that year were below the average number. The weather was severe, the people suffered, and the death-rate in the first quarter of the year 1858 was heavier than it is on an average; but the birth-rate in the same quarter, though lower than in the three previous winters, was above the average. The population of the country is still increasing. 171,001 births and 125,902 deaths were registered in the first ninety days of the year; and the natural increase of population in that period was therefore 45,099, or 501 daily. The natural increase in the winter quarter of 1857 was 687 daily. The falling off in the increase of population is referable to the excessively high rate of mortality during the past winter; for the births exceeded by 7 daily the births in the winter of 1857. The daily natural increase of population in the United Kingdom was probably about 750."

The meeting on Wednesday, for the presentation of degrees of the University of London, was particularly interesting. During the last academical year 224 candidates matriculated; thirty-five passed their first examination for the degree of Bachelor of Medicine, sixty-six passed the examination for the degree of Bachelor of Arts, thirty for Bachelor of Medicine, six for Bachelor of Laws, five for Master of Arts, twelve for Doctor of Medicine, and one for Doctor of Laws. Lord Granville delivered an admirable address, congratulating the University on the recent changes which had led to the infusion of new blood into the council, and defending the liberal plan of throwing open the honours of the University to the students of other than the affiliated Colleges. He exposed the fallacy of those who think lightly of the value of University distinctions; and urged both the successful and unsuccessful candidates for honours, to derive, both from success and failure, the incentive to further exertion.

The *Times* is very angry because the statue of Dr. Jenner is placed in Trafalgar-square beside Sir Charles Napier. Admitting such men as "Harvey, Hunter, and Jenner to be quite as worthy to be held in public honour as any warrior who ever lived," the objection is urged that in the public places of a great town "it cannot be desirable to group together inconsistent figures." There is something in this; but the answer is that the figures of great men who have merited well of their country are not "inconsistent," however different their services may have been. Still we should have been quite as well pleased to see Jenner's statue at the north-west angle of the square, opposite the College of Physicians. Jenner has nothing to gain by any reflected glory from Sir Charles Napier.

The *Globe* concludes an article on the Anatomy Act, in which the view we took of the reversal of the sentence on the master of the Newington workhouse is supported, by the following observations, which are well worthy of the attention of the educated classes: "Perhaps no study can more strictly conduce to the loftiest feelings than the examination of the human structure. Properly carried out, it is consistent with every respect for the departed. Again, the most educated classes are those which ought best to appreciate such considerations; and it would unquestionably be advantageous for the progress of science, and for the collateral morals of this subject, if the educated class were more frequently to set the example of freely permitting the use of human remains for the purposes of study, instead of leaving the pauper class to supply the want, either because they are more helpless, more negligent, or because they have not the sharpness to keep a watch upon the masters of workhouses."

The first annual report of the Board of Superintendence of Dublin Hospitals, has been presented to both Houses of Parliament by command of her Majesty. The report states that the improvements now in progress in the Westminster Lock Hospital, in which up to the 31st of March, 1857, the number of beds was limited to forty, will give an accommodation of 150 beds. The importance of the House of Industry Hospital, in an educational point of view, is alluded to. The Board commend the promptitude with which the governors of Steevens' Hospital have carried out the improvements recommended by the Hospital Inquiry Commissioners. They advise an addition to the accommodation for chronic medical cases in the Meath Hospital, so soon as the funds shall admit of it. It is stated that in compliance with the recommendation of the Committee of the House of Commons of 1854, the amount of donation requisite to constitute a Life Governor of the Rotundo Lying-in Hospital, has been reduced from £100

to £50, and the subscriptions of Annual Governors from £10 with £10 entrance, to £5, with £5 entrance, but that the removal of the restriction of the number of governors to sixty, cannot be effected under the present charter. The mistaken nature of the feelings which prompt the governors of the Hospital for Incurables to prevent the performance of post-mortem examinations, is pointed out. The condition in which the Cork-street Fever Hospital, the Coombe Lying-in Hospital, and St. Mark's Ophthalmic Hospital were found, is commended. Some useful tables are given in an appendix.

Petitions to Parliament on medical subjects have been very numerous during the week. Most of them are on the subject of Poor Law Medical Reform. A few support the different medical bills, and one, which we suppose is to help Mr. Duncombe in his notable scheme, was presented by Lord Gode-rich, from the practitioners and adherents of Dr. Coffin's medico-botanic system of medicine in Meltham-mills, Yorkshire, praying that the claims of the practitioners and followers of that system may be taken into consideration by the House in any legislation in reference to the medical profession. We must wait for the debate on the second reading of Lord Elcho's bill next Wednesday, to be able to judge of the present temper of the House of Commons on the rival bills.

## REVIEWS.

*Rheumatism: its Nature, Causes, and Cure. Gout: its Nature, Causes, Cure, and Prevention.* By JAMES ALEXANDER, M.D. Member of the Royal College of Physicians, Fellow of the Royal College of Surgeons. 8vo. Pp. 266. London. 1858.

Dr. Alexander states in his preface, that in the first few years of his professional life he was taught by reading, lectures, and clinical instruction, to know rheumatism when he saw it; but that he never could obtain from any source a satisfactory explanation of the true nature of the malady; the cause, in fact, of those symptoms which, taken in the aggregate, constitute the morbid phenomena which we recognise as this disease. Among his instructors, "one would rush boldly through by asserting 'that it was caused by inflammation of the fibrous tissues;' another would say, 'that it was, no doubt, dependent on the retention of lactic acid and its salts in the circulation.' Very strong grounds for doubting the correctness of the first opinion have long existed; and after having searched long and hopelessly for any evidence of the retention of lactic acid and its salts, as the *materies morbi* of this affection, I was compelled to abandon that theory, as based equally on a delusion and a myth. The doubts which arose during my pupilage followed me into practice, and I was never able to prescribe for a case of rheumatism without feeling that I was committing a legalized quackery." From this statement of our author we were certainly led to expect to find a view of the nature of rheumatism proposed by him which should not only have the merit of novelty, but should also be supported by evidence of a very strong and convincing character. In this, however, we have been altogether disappointed, for not only has his theory from time to time been proposed by others, but it is likewise one which is altogether unsupported by one tittle of evidence, and entirely opposed to facts which have been experimentally established. Throughout the whole of his little work Dr. Alexander has been greatly aided by adopting a method, which is by no means confined to himself, of totally disregarding facts that are at all at variance with his preconceived views, and of making new data upon which to build up hypotheses, regardless altogether of their claims to truth. To show that we have not made these remarks without due consideration, we will select a few points as examples of his mode of reasoning.

In the first place, he disbelieves the view of rheumatism being connected with the abnormal presence of lactic acid in the blood, but gives no reason for his scepticism. Its presence has certainly not been clearly demonstrated, but there are many arguments in favour of such an opinion; amongst these

the fact that injections of lactic acid into the peritoneal cavity in the lower animals have been followed by the production of deposits upon the valves and lining membrane of the heart. We say that this may be quoted in favour of the view, although we would by no means lay great stress upon the point, as the effect of other acid bodies has not yet been tested. That lactic acid has not been demonstrated to exist in abnormal quantities in the blood of rheumatic patients is not a subject of astonishment to any one acquainted with chemistry, as it is a body difficult to recognise in small quantities, and by no means readily separated from other organic principles with which it must necessarily exist when contained in the circulating fluid. Dr. Alexander thinks that all the phenomena of rheumatism are easily explained by assuming the presence of urate of soda in the blood, and the whole of his hypothesis of the nature of the disease is based upon this assumption. Now, what are the proofs of the truth of this theory? We believe that it is altogether an error. The author does not attempt to show by analysis that it is present, yet the detection of this body in the blood at the present day is a matter of the greatest ease. Nay, he shuts his eyes to the results obtained from the examination of the blood in numerous cases of acute rheumatism, published by Dr. Garrod in the "Medico-Chirurgical Transactions" of 1854, which proved the absence of any such impurity in this affection; although he quotes the results of the same author to prove the constant presence of urate of soda in the blood of true gout. Dr. Alexander's hypothesis, therefore, is not only not supported by any direct evidence—and, if correct, it might readily be so—but it is in direct opposition to the results of all the researches which have been instituted upon the subject.

In the first chapter many pages are devoted to the physiology of uric acid; and here it becomes apparent that the physiological and chemical views put forward are by no means such as would be agreed to by those who are usually considered competent to judge on these matters. Who, for example, having the slightest knowledge of organic chemistry or physiology would subscribe to the following remarks:—"Nascent urea meeting with carbonaceous impurities, the products of excessive oxidation, which are unable to escape from the circulation by the ordinary emunctories, becomes reconverted into uric acid, etc.?" Who ever heard of uric acid being built up in the animal economy? That it can be broken up into urea and other compounds less complex than itself, not only within the body, but also by artificial means, is a fact well known; but the formation of this acid from urea and carbonaceous matters, is in the very highest degree improbable, and totally devoid of all proof. No little of our author's explanations seem to depend on this gratuitous formation of uric acid. In this way, he makes the kidneys kindly give assistance to the great decarbonizing organs when the functions of the latter are impaired. This view is fully set forth in the following quotation, which is, at the same time, one which will give a very good idea of the chemical, physiological, and pathological reasoning contained in the work:—"And where the carbonized products of oxidation are generated so largely that the ordinary emunctories—the lungs, the liver, and the skin—are unequal to their elimination as rapidly as they are formed, they are consequently retained in the circulation, and form fresh combinations. Hence uric acid; and hence the mode in which the kidney fraternises with its brother scavengers, the lungs, the skin, and the liver, in the purification of the highways and byways of our bodies from those nitro-carbonaceous impurities which have already served their purpose in the animal economy, and which, by their accumulation and retention in the circulation, would, were it not for the compensatory and vicarious action thus set up by the kidneys, be productive of derangement, disease, and death." Among the arguments adduced in favour of urate of soda being the morbid matter in rheumatic blood, is the fact that in this disease there is often a copious deposit of urates in the urine; but it must be remembered that such a phenomenon occurs in many other affections totally unconnected with rheumatism, and that, instead of being evidence of the existence of the same in the circulating fluid, it argues strongly for the opposite view; for if the kidneys excrete freely, the chance of the blood being pure becomes much the greater. Dr. Alexander, to reconcile the difference between rheumatism and gout, has recourse to a most peculiar mode of explanation; he considers that in the former disease (rheumatism) the blood, instead of being deteriorated, is in fact too healthy, for, he says—"Now, rheumatism does not

depend on poverty, but *purity* of blood," reminding us much of Lady Teazle "absolutely dying from too much health."

By means of his hypothesis, our author explains certain symptoms of this disease in a way which most pathologists will be apt to consider somewhat crude and mechanical, when he remarks:—"The pain of rheumatism in the acute fibrous form of the disease, is dependent on the particles of urate of soda which accumulate in the myolemma and sarcolemmas of the muscles, pressing on the nervous fibrillæ which traverse these structures, and temporarily paralysing them by the pressure occasioned by their accumulation. The patient, though restless, is unable to move, and tells us he is paralysed, which is literally the case for a time. With the removal of the morbid matter the motor power in some degree returns, but there is frequently a want of power for some time after a severe attack."

A similar kind of explanation is given to account for the occurrence of head affections in rheumatism—in fact, that they depend on the actual impediment produced by particles of urate of soda.

The pathology of any disease might be most readily cleared up if such modes of explanation could be employed, but in the above quoted passages everything is purely hypothetical, and altogether contrary to established facts. Can it be proved that rheumatic fever or acute fibrous rheumatism, however frequent may have been the attacks, and however great the alterations produced by it in the articular structures, was never followed by a deposition of urate of soda? We could bring forward abundant evidence to show that no such phenomenon ever takes place. And, again, we know of no observations showing that crystallised urate of soda ever exists in blood. Were it contained in such form, the microscope would at once reveal it. We should suspect Dr. Alexander is not much accustomed to blood analyses.

In the chapter devoted to the treatment of acute rheumatism we find nothing novel—the same remedies are made use of by Dr. Alexander as by others. Opium, salts of potash, colchicum, lemon juice, cinchona, etc. Their therapeutic properties, however, are explained according to his own theory; and from our present amount of knowledge of the intimate action of remedies, could as readily be made to agree with any other. His explanation of the good effects of opium in acute rheumatism, and of colchicum in gout, is as follows:—"Opium, by diminishing the irritability of the heart, causes fibrillation of the blood to go on less rapidly; and by checking the rapidity with which destructive assimilation takes place, it causes it to be more effectually performed, and the effete albuminous matters to be resolved into urea instead of uric acid. In the treatment of acute rheumatism, our object is to check the rapidity with which oxidation is going on; in gout, on the other hand, our whole treatment is directed to its more rapid fulfilment." And again: "Opium is the curb by which we check the pace at which oxidation of tissue goes on, colchicum the spur by which we promote it."

In one part of his treatment, however, Dr. Alexander differs from that adopted by most Physicians; and, as it is a point of some considerable importance, we will dwell a little upon it. It is with regard to local depletion of the affected joints in acute rheumatism. We believe that it is usually considered the most judicious course not to apply leeches to them, as the chance of permanent local mischief being produced by the disease is very small, and from leeching being usually thought to favour metastasis. In the present treatise, however, an opposite plan appears to be advocated, for it is asserted that "the application of leeches will generally relieve the inflammation of the synovial membrane that is set up from contiguous irritation; and they are beneficial not only in this respect, but, by diminishing the vitality of the parts, they lessen the chance of metastasis from reaction, under which the morbid matter is thrown into the circulation, to again take up its quarters we know not where. It is better, therefore, to leech at once, with the view, not only of relieving the pain, but of diminishing the tendency to cardiac complications."

From our author's views on the pathology of rheumatism and gout, namely, that the former is connected with increased waste of tissue from over-oxidation of the system, the latter with diminished oxidation; and that opium checks oxidation and colchicum spurs it on, it must, we think, be a matter of no little difficulty on some occasions for our author even to know which to prescribe, for the combination, according to his own showing, must be absurd. And, again, there must

be a point in his supposed transition of one affection into the other, where neither opium nor colchicum can be of any avail; a point, in fact, where there is neither an increase nor decrease of oxidation going on,—a time, in short, of comparative health. Experience, however, shows that both remedies may be at times combined with advantage, and that their influences are by no means antagonistic of each other.

In concluding our notice of that portion of the volume relating to rheumatism, we cannot help wondering why Dr. Alexander, holding his present opinions, should not equally commit a "legalized quackery" when prescribing for a case of rheumatism, as at the time when he considered the disease to consist of an inflammatory condition of the fibrous tissues, and dependent on the presence of lactic acid in the blood. Our space will not permit us to say much about the chapters devoted to gout. But this need not be regretted, for the author, in treating of rheumatism, which he considers so closely related to gout, necessarily anticipates many of his views, which are by no means original, as far as the presence of urate of soda in the blood and its deposition in the affected parts is concerned; and that portion of his hypothesis connected with deficient oxidation is by no means proved. One interesting case (the only case in the book) of retrocedent gout is related of an individual who was imprudent enough to cover his foot during the acute affection with snow, which produced sudden syncope and difficulty of respiration.

As far as the treatment of gout is concerned, the only point of novelty we notice is the proposal (based on Dr. Alexander's view of defective oxidation) of the patient's inhaling oxygen gas:—"Of its applicability to the treatment of gout, and the great advantages to be derived from it, no one who reflects on the true nature of the disease can for one moment doubt." No proof, however, is adduced to show this great advantage; but Liebig's opinions are pretty freely quoted, although we cannot see their applicability to the subject in question. The work concludes with a chapter on the prophylactic treatment of the disease; and the following deductions are drawn:—"That no man need suffer from gout who will steadily adopt those rational means which science and experience have proved to be so effectual in preventing the formation, accumulation, and retention in the circulation of that morbid matter which is the cause of gout."

But, again, our author is compelled, in justice to those who would rely on medicine alone, without any modification of their habits of life, to admit the poverty of medicine, and to deplore with them, that—

"The ills that they themselves procure,  
Must be their schoolmasters."

*A Dictionary of Medical Science.* By R. DUNGLISON, M.D., LL.D. Fifteenth edition. London: 1858. 8vo, pp. 992.

*A Dictionary of Terms used in Medicine and the Collateral Sciences.* By R. D. HOBLYN, A.M. Eighth edition. London: 1858. Fcp. 8vo, pp. 660.

It is scarcely necessary to do more than refer to the fact of the above dictionaries having reached one to fifteen, and the other to eight editions. But we must add that Dr. Dunglison has added some "six thousand subjects and terms" to his work, which has also been carefully revised, and offers stronger claims than ever to the favourable attention of the Profession.

Mr. Hoblyn has altered the size of his volume to render it "a uniform companion to the popular series of Manuals of Medical Science," and has incorporated in the alphabetical arrangement several articles which have been appended in former editions.

## PROGRESS OF MEDICAL SCIENCE.

### Selections from Foreign Journals.

#### ON ULCERATIVE ANGINA AND DIPHTHERIA.

By M. BOUCHUT.

M. Bouchut observed, in a recent lecture, that the greatest confusion has arisen from designating by the same appellation, *angine couenneuse*, a variety of affections essentially dis-

tinct from each other, as the syriac ulcer, malignant gangrenous angina, Huxham's sore throat, Fothergill's angina, diphtheritis and croup; affections different in their nature and in the treatment they call for. At the time of his lecture, he had in his wards at the St. Eugenie cases which well illustrated the difference, viz. two of ulcerative or gangrenous angina which came on during scarlatina, two which were unattended by any eruption, one case of *angine couenneuse* (or diphtheritis), properly so called, and a case of croup.

The ulcerative or gangrenous form of angina is attended with more or less loss of the tonsil, and the formation of an irregular ulcer. Whether it is primary or secondary, there is observed on the first day a greyish-white spot on the tonsils and uvula, and next day there is lividity of the surface or loss of substance, the ulcer that ensues much resembling a syphilitic one in aspect. By proper treatment the extension of the ulcer may often be prevented, but if the disease assume a malignant form, the extension becomes great, accompanied by gangrenous odour, and our therapeutical succours can do little for its arrest, and the patient sinks from the fever and ensuing prostration. Emetics should be early administered so as to produce free vomiting, and then glycerine should be applied (or, if the child is old enough, used as a gargle), every hour, day and night. M. Bouchut has now used it in more than 40 of these cases (of the non-malignant form), and has been quite surprised at the rapidity with which cleansing and healing of the ulcer has ensued. In many of these he has used glycerine alone, but in others he has also given the chlorate of potass (a medicine he thinks much overpraised) internally.

The true form of *angine couenneuse*, or diphtheritis, as exhibited in a child, had continued for twelve or fifteen days quite local, false membranes covering the tonsils and uvula, without destruction of substance, and only giving rise to dysphagia and hoarseness with little or no fever. At that time, however, the fever became intense, the false membranes invaded the nose, Eustachian tube and larynx, diarrhoea and prostration set in, and the patient was carried off. It is a diphtheritic intoxication, of the true nature of which we are ignorant. Therapeutical agents are of no efficacy unless the disease continues limited to the pharynx, and without complication of the general affection of the economy due to epidemic influence. Nothing could better prove that the nature of disease consists less in these somatic lesions than in determining general causes, than the fact of the existence of epidemics, the symptoms, course, and terminations of which are so different according to the places and the periods at which they appear. Contrasting the disastrous effects produced by diphtheritis in certain small localities, with its almost constant curability when existing in the sporadic form, we naturally inquire how a lesion, apparently so slight, could be followed by such different terminations, unless there existed at the same time as this, another general influence capable of impressing upon it so fearful a gravity. The epidemic influence is, in fact, the unknown cause from which all the danger of the disease is derived.

Whether it exists in the sporadic or epidemic form its treatment is the same. The indication is the mechanical or chemical removal of the false membranes, and the prevention of their re-formation by the aid of contra-stimulant and antiplastic remedies. The first of these is best fulfilled by the exhibition of emetics every or every other day. The membranes may also be destroyed by the hydrochloric acid, so much approved of by MM. Bretonneau and Trousseau, by nitric acid, nitrate of silver, and the actual cautery. Although these means are, no doubt, often of service, M. Bouchut does not resort to them; but if he did, he would give the preference to the hydrochloric acid, rejecting the actual cautery as a barbarism. The means he employs is glycerine, which he finds to be a very efficient solvent of false membranes, when not too hard, and especially when they are muco-fibrinous, rather than fibrinous. There are great differences among these false membranes to be noted. Some are but slightly resisting, whitish, pulvaceous, and formed of a soft exudation filled with muco-pus and granular bodies, in the midst of numerous epithelial cells, and almost destitute of fibrine; others, which are more resisting, consist of a greyish albumino-fibrinous exudation, contain a little more fibrine than the former, and are easily torn. Others are entirely fibrinous, whitish, and tough, exhibiting under the microscope filaments of well-marked fibrin, amidst which a small quantity of epi-

thelium and granular bodies are observed. Of these three varieties of false membranes, the first two readily dissolve in glycerine, while the last does so only incompletely. These latter also become softer and less bulky, but they do not entirely disappear under the action of glycerine.

For the purpose of preventing the reproduction of the false membranes various alternatives and specifics have been employed. Mercury, M. Bouchut believes, risks doing as much harm as good; and he thinks better of divided doses of antimony, which, with proper precautions, may be given to children. Baron strongly recommends carbonate of soda or the Vichy waters, both as a preventive and a solvent agent, but from this M. Bouchut anticipates little. Chlorate of potash, highly useful in ulcerative and gangrenous angina, giving rise to purulent or pultaceous products, and in stomatitis, has proved of no efficacy whatever in his hands in numerous cases of diphtherite and croup.—*Gazette des Hôp.*, 1858, Nos. xliii. and xlvii.

It may be as well to append to the above a few other notices that have appeared in the French journals. M. Duché, writing from Ouanne in the Department of the Yonne, where the disease prevails epidemically, declares that he has found all treatment useless, the removal of the false membranes being followed by their rapid reproduction, and the invasion of the deeper seated air-passages. M. Barth, in his recent report to the Academy of Medicine upon the epidemics that prevailed in France in 1855, states, that it was always observed that the victims became very numerous when the disease was left to itself, while the recoveries notably increased when it was promptly treated by emetics, the application of caustics, and the employment of tonics. M. Pichenot states that during an epidemic at Censerey, Department of Côté-d'Or, the employment of emetics prior to the appearance of the membranes, the removal of these by alum, and then the repeated application of nitrate of silver, this treatment being combined with the use of tonics and strong broths, constituted an efficacious plan of management. Of 125 children, presenting all varieties of the disease, 77 recovered and 48 died. M. Loiseau of Montmartre, declares that during fifteen years that he has been in the habit of employing alum and tannin through the medium of laryngo-tracheal catheterism he has not lost a case! Most persons will agree with M. Trousseau in thinking that he had not the epidemic form of the disease to deal with. M. Beau relates some cases in proof that when death does not take place by the extension of the disease to the larynx and the production of secondary croup, it may do so from fibrinous concretion in the heart; and M. Perrochaud, who we are glad to find is about publishing an account of the interesting epidemic that visited Boulogne last year, states that he also has met with a case of this description. M. Ollivier of Ingrandes, states that during an epidemic of scarlatina with ulceration and couenneuse angine (evidently mistaking the disease, in the manner M. Bouchut has pointed out in the lecture), the best results attended cauterizing the parts with his pure acid nitrate of mercury and the external employment of leeches.—*Gazette des Hôp.* Nos. 36, 39, 42, and 48.

#### EXCERPTA MINORA.

**Arsenic in Chorea.**—Dr. Rice states that he has of late treated severe cases of chorea with great success by means of arsenic, the treatment occupying only from two to six weeks. He says: "I am no believer in specifics, but I think arsenic is as sure to cure chorea as bark is to cure ague; the remedy must be watched and used with caution, and then it is entirely safe." He employs Fowles's solution, giving other medicines as adjuvants as the case requires them.—*Boston Journal*, 1858, p. 78.

**Influence of Prolapsus Uteri on the Urinary Passages.**—Professor Düben exhibited to the Stockholm Medical Society, a preparation showing an incomplete prolapsus uteri with great prolapsus and inversion of the vagina, and in which the ureters, compressed by the protruding uterus, had, as well as the pelves of the kidneys, undergone dilatation, the substance of the kidney itself becoming atrophied. Professor Retzius stated that he had met with a subject in the dissecting-room having a considerable prolapsus uteri. Both kidneys were completely atrophied, while their pelves were exceedingly expanded, and the ureters were widened and twice as long as in the normal state. The bladder was very large and thickened at its lower part. That portion of this organ where the ureters enter was compressed between the arcus pubis and the prolapsed and

enlarged uterus. The urethra was also strongly curved, and pressed upwards against the arcus. It was also elongated, and a fold of its mucous membrane hung without its orifice. The prolapsus had given rise to retention of urine and its consequences.—*Monats. für Geburtshunde.* Band ix. p. 74.

**Freedom from Phthisis among Colliers.**—M. Francois has recently brought this subject before the Belgian Academy of Medicine. Attached to a colliery, he has since 1818 observed that while the miners suffer from anæmia, asthma, bronchorrhæa, affections of the head, carbonaceous expectoration, and pulmonary emphysema, and die prematurely, they are remarkably free from phthisis, although their relatives enjoy no such exemption. He states that this observation has been confirmed by numerous colliery practitioners. M. Martens is disposed chiefly to attribute the immunity to the great degree of atmospheric pressure the miner is subjected to. The Academy has resolved to request the Government to obtain some exact statistical information on the subject.—*Bullet. de l'Acad. Belge*, tom. xvi. pp. 556 and 597.

**Injection of Sesquichloride of Iron in severe Menorrhagia.**—Dr. Breslau relates a case in which very obstinate and copious menorrhagia, accompanying a retroflexed state of the uterus, after resisting various other means, speedily yielded to an injection of equal parts *liq. ferri sesq.* (*Bavarian Pharmacop.*) and distilled water.—*Monatschrift für Geburt.* B. x. p. 274.

**Inhalation of Sal-Ammoniac in chronic Catarrh.**—Dr. Gieseler speaks highly of this. A drachm of dry muriate of ammonia is heated over a spirit lamp, and the patient inhales the vapours. He says the same means is of service in scrofulous affections of the eyes, and in catarrh of the bladder.—*Froriep's Notizen*, No. 20.

**Digital Compression in varicose Aneurism.**—A man, aged 27, came under Signor Gherinis' care with a varicose aneurism the size of a walnut, situated at the bend of the arm, the result of a venesection performed forty days before his admission into the Milan Hospital. Three assistants having volunteered to succeed each other in keeping up digital compression, this was executed at about the middle of the arm, so as nearly to arrest the passage of the current. In about three and a half hours the pulsation in the tumour ceased to be felt, this becoming small and hard. The compression was now discontinued, and cold applications made to the tumour, under the use of which this continued to diminish in size. The patient was dismissed as cured ten days after, and when seen some days later, no signs of pulsation in the spot were to be found.—*Omodei Annali*, vol. clxiii. p. 99.

## PROVINCIAL CORRESPONDENCE.

### IRELAND.

DUBLIN, May 4, 1858.

THE last meeting for the present session of the Pathological Society of Dublin was held on Saturday last, in the Anatomical Theatre of Trinity College. The President, Dr. Hutton, on taking the chair, alluded in feeling language to the sudden and melancholy event which had occasioned the postponement of the meeting from the previous week, and to the loss the Medical School and Scientific Societies of Dublin had suffered in the death of Professor Harrison. After a communication by Dr. McDowell, the essay which had been awarded the Society's gold-metal was laid upon the table, and the corresponding sealed envelope having been opened, Mr. Glascott Richard Symes was called upon, as the author of the essay, to receive at the hands of the President his well-earned mark of distinction. Dr. Hutton observed that the Council felt that on no previous occasion had the recipient been better entitled to their medal, and he complimented the writer on the industry and ability he had displayed in the essay, as well as on the manner in which he had illustrated the subject, the "Diseases of the Breast," with numerous cases observed by himself. The President then declared the Society adjourned until next session.

The sixth annual report of the proceedings under the Medical Charities Act of the Commissioners of Irish Poor Law has been presented to the Lord Lieutenant, and contains some interesting and valuable information in reference

to the Medical Charities of Ireland, from which I shall endeavour to cull a few of the leading points.

It appears that in the year ended September 30th, 1857, the number of cases in which domiciliary medical attendance was afforded was increased, as compared with the preceding year in Ireland, by 8057. The expenditure of the dispensaries throughout all Ireland, which last year amounted to £90,460, has not varied during the last five years by more than £2020. The expenses for 1856-57 were,—medicines and medical appliances, £16,179; rent of dispensary buildings, £6709; books, stationery, &c. £1098; salaries of Medical officers, £60,199; salaries of apothecaries, £1757; incidental expenses, £4518. The average poundage on the valuation of Ireland for dispensary expenses in 1857 was 1-82d. The number of cases of vaccination last year was only 47,855, against 84,131 in 1856. The commissioners calculate that the former number falls short of what it ought to have been by nearly 100,000; and that the number of persons in the country unprotected from the consequences of exposure to variolous infection is so great as to justify the expectation of the most serious amount of loss of life in the event of the occurrence of a severe epidemic of small-pox. In the absence of epidemic influences, itinerant inoculators, by the practice of their mischievous trade, keep the contagion of small-pox permanently active in numerous localities, thus causing alike increased mortality, loss of vision, and greater burdens on the public. The Commissioners represent that nearly all this loss of life, and almost all the other evils alluded to, are preventable by the enforcement of a complete system of efficient vaccination. For legislation on this subject, as well as for the introduction of a registration of births and deaths, the Commissioners express an anxious desire. Between the 2nd and 21st of October, about the time when some very characteristic cases at West Ham, near London, gave rise to much alarm, fifteen cases resembling Asiatic cholera, of which two proved fatal, occurred in a certain part of the small town of Portaferry, in the county of Down. Scarletina declined from 2469 cases in the three months ending 31st of March, to 618 in the last quarter of the year. The number of cases of fever registered at the dispensaries during the quarter ending 30th of June was 3224, while for the last quarter of 1857 it was only 1255. The returns from the Workhouse Fever Hospitals in 1857 show a considerable reduction in the number of fever patients as compared with the number of those admitted in 1856. From the foregoing facts the Commissioners "think it may be concluded that there is at present no reason to apprehend an immediate return of fever in an epidemic form in Ireland; and this circumstance forms an important addition to the existing testimonies of the continued advance of the country in prosperity."

The annual examination for the prize of five guineas given by the Council of the Apothecaries Hall to the best answer on a subject in Pharmaceutical or Physiological Chemistry, was held for the present year on Monday and Tuesday, the 3rd and 4th of May, when Mr. William Madden was awarded the prize, and Mr. David Hewitt the certificate, as the best and second answerers on the "Chemistry of Assimilation."

The students of the College of Surgeons in Ireland have presented Dr. Mapother with a tea and coffee service and salver, bearing the following inscription:—"Presented to Edward Dillon Mapother, M.D., Queen's University, by the students of the Royal College of Surgeons, in appreciation of his talents as a teacher of Anatomy and Physiology."

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following gentlemen were, on Tuesday last, elected examiners for the ensuing year:—J. Smyly, Richard Tubhill, T. Byrne, Richard Butcher, M. Stapleton, B. W. Richardson, and Edward Stoker, Esqrs.

May 5.

P.S.—The account of Sir Philip Crampton this morning is, that "there is no change, he had a quieter night."

SAND BATHS.—At Cannes, besides the usual aquatic bathing, sand baths are now in vogue on the warm beach, the patient being imbedded up to the neck in the sand. This is an Egyptian custom.

SIR JAMES M'GRIGOR.—The Medico-Chirurgical Society of Aberdeen, have addressed a graceful letter of sympathy to Lady M'Grigor on her recent bereavement, expressing their high opinion of the private worth and public services of one of the founders of their Society.

## GENERAL CORRESPONDENCE.

### ENCOURAGEMENT OF HOMŒOPATHY.

LETTER FROM DR. STALLARD.

[To the Editor of the Medical Times and Gazette.]

SIR,—I am one of those who believe that the first duty of the physician and surgeon is to render assistance to any suffering fellow creature who may demand their services. This is their profession, and society looks to them for its fulfilment to the best of their ability and opportunity; for all know how often the best intentions are frustrated by the whims, habits, vices and prejudices of their patients. Nor do I believe that we can rightly leave any in the exclusive hands of those whose system of treatment is founded in absurdity and fraught with danger, when the alternative is offered to us of watching the case, and it may be, by a firm remonstrance at the proper moment, of saving life.

None know better than the most enlightened members of the Profession, the difficulty there is in forming a correct estimate of the value of special remedies and particular modes of treatment; and it is notorious that very many diseases get well without any treatment beyond a careful attention to diet and regimen. It becomes us, therefore, to exercise the greatest forbearance towards that happily small section of society, who, without having received a special education, have been misled by the specious arguments of a seductive and plausible fallacy. How often has ill-directed zeal by some violent tirade disgusted a patient and driven him irretrievably to adopt a system which he was at first more than half afraid to trust? How often has a copious vocabulary of abusive epithets offended the prejudice of friends, and led even the patient to regard the speaker in an unfavourable light? These considerations apply with peculiar force where the practitioners are educated men—qualified by a diploma, move in society with a reputation for candour and honesty, to which we can offer no valid objection; and whom we are bound occasionally to meet as gentlemen, even if we object to consult with them as physicians. Are we not certainly bound to take advantage of every opportunity of stating our opinions and offering our advice when the patient is under the influence of such refined error, and this even more sedulously than when the professor is obviously illiterate and ignorant? Such being so, upon what ground have we the right to refuse our required advice, the patient being still attended by a Homœopath, or being resident, it may be, in a water-cure establishment? The only pretence for doing so is the utter incompatibility of our ideas of treatment. This it is our duty at once and fully to represent. Respect for the principles of our art and for our own character, alike demand that we should undertake the treatment of no disease, whether medical or surgical, without the privilege of employing all the resources at our disposal. But in fact, do the Profession ever come in contact with the Homœopaths or Hydropaths on this point? It is almost impossible; for when neither party consents to the meeting, it is the patient who chooses the system of treatment to be adopted. When, however, brought about with the approbation of either, it cannot be to consider treatment, neither, I suppose, being dishonest enough to forego his principles. It must, therefore, be for other reasons, and of these I can conceive and have known many. The patient may tell us plainly he wishes our opinion, and not our treatment; are we, therefore, to refuse it? A surgeon is required specially to open an abscess, to amputate a limb, to pass a catheter. He may go a hundred miles for the purpose, and never see his patient again. These are cases in which he does not even assume the responsibility of the operation; and in all these is he to refuse his attendance, because he has not the entire control of the case, or because the patient is attended by an heretical professor? Or, again, is a physician, when summoned to the inmate of an hydropathic institution, to refuse to go because he will be compelled to meet the medical superintendent, although the question proposed to him for solution is one of diagnosis, or it may be, but to satisfy the anxieties of friends? Once more, suppose a physician be required to watch the progress of a fever in the case of one dear to the whole circle whose whim it is to be treated with Homœopathic

globules. Are we to refuse because we shall be compelled to acknowledge the existence of a Professor of Homœopathy, and to watch the case in conjunction, if not in consultation with him? Are we to refuse a simple act of humanity by the fear of humiliating our Art? I say emphatically,—No. The duty of the Physician or Surgeon is clear. It is to render his advice firmly, honestly, and to the extent of his opportunity, as well in the face of an heretical practitioner as behind his back; with no tampering with principles, to which every act of his daily career is a denial, but with a consideration and forbearance which may enable him possibly to convince of error, and thus to render a service to his art, which, if indeed for a moment placed (but not by him) in a humiliating position, has not necessarily been dishonoured thereby.

I am, &c. J. H. STALLARD.

Licentiate of the Royal College of Physicians,  
Physician to the Great Northern Hospital, &c. &c.  
12, Welbeck-street, Cavendish-square,  
May 6, 1858.

#### LETTER FROM THOMAS R. EVANS, M.D.

[To the Editor of the Medical Times and Gazette.]

SIR,—In your impression of April 17th, "Justa aut Nihil" asks, "How is he to act in the following cases?"

"A man smashes his leg, his son divides the radial artery, and his wife has femoral hernia. They all with one consent hate physic as they do poison, and they will have none of it; shall I let the first die of mortification, the second of hæmorrhage, and the last of intestinal obstruction, because of their unbelief? Suppose these three persons are rank Homœopaths, etc. etc."

The answer to this seems to me plain. If a patient abuses the regular practitioner, and believes in Homœopathy, let him show that he has faith in his new creed by trusting himself to the treatment of its professors; if, when danger presses, he loses faith in his theory, let him discard his Homœopathy, and he will find ready help from the regular practitioner. According to the views of "Justa aut Nihil," "any man who professes to attend for a fee, is bound to do so when that fee is offered;" concede so much—but that does not bind any honourable man to meet a Homœopath and consult with him upon the case.

Let Homœopathy stand or fall by its own worth or worthlessness; if "Justa aut Nihil" has no faith in his infinitesimal system, renounce it, and then he may claim and obtain the help he seeks from the regular practitioner, but do not let him seek to mix the two systems.

Let Homœopathic patients feel that they must depend upon the Professors of that system for relief, or abjure it before they can claim the help of the ordinary Physician or Surgeon. Why should we permit our Profession to be humiliated in the persons of its professors by the requirements of the public? They may make their own choice of a system; and, having done so, let them abide by their own acts. They are free agents, and if they choose quackery let them have their choice; but let them not ask the members of an honourable Profession to bolster up quackery for the sake of a fee, nor attempt to bully them into submitting to meet Homœopaths on equal terms, lest, forsooth, they should lose support.

I am, &c. THOMAS R. EVANS, M.D. M.B.C.S.E., &c.  
Cotteshall, May 4, 1858.

#### CÆSAREAN SECTION.

LETTER FROM DR. ROBERT GREENHALGH.

[To the Editor of the Medical Times and Gazette.]

SIR,—I regret my unavoidable absence at the reading of my paper upon "Extensive diseases of the osseous system, necessitating the performance of the Cæsarean section," at the Royal Medical and Chirurgical Society, on April the 13th, as I should have been able at once to satisfy the doubts expressed by certain Fellows, and have spared you the trouble of reading this communication, which I submit to your kindness for insertion in your important Journal.

The first doubt has reference to the size of the pelvis, which was supposed to have shrunk. In answer to this, I

can assure you, that the diameters were carefully measured before and during maceration, and found to correspond (allowing for the soft parts) with the dimensions stated in my paper, hence there could have been no appreciable shrinking, as supposed by the gentlemen previously referred to.

Second doubt: could not premature labour have been induced? This could not be effected, because the os uteri could not be reached by any possible mode which appeared to me or Drs. Rigby, Ramsbotham, Druitt, and others who examined the case some time before the operation. Fortified by the opinions of such authorities who were present, I need not say more to defend my practice against the observations of any gentleman who was not present. It must be remembered that the bones were not soft and yielding, but exceedingly brittle, so that were I disposed under ordinary circumstances to believe in the effects of "air-balls," I should certainly not be disposed to trust so serious a case as the one in question to any such questionable practices.

I am, &c.

ROBERT GREENHALGH, M.D.  
11, Upper Woburn-place, May 3, 1858.

#### NAVAL MEDICAL REFORM ASSOCIATION.

LETTER FROM T. HOLMES, Esq.

[To the Editor of the Medical Times and Gazette.]

SIR,—Will you allow me to inform the subscribers to the late Naval Medical Reform Association through your columns, that the remaining surplus of the funds of that Association, amounting to ten guineas, derived principally from the funds of the late sub-committee from St. Bartholomew's Hospital, made up to the above amount by a liberal contribution from J. Allen, Esq., of Liverpool, the treasurer, has been paid to the Royal Medical Benevolent College in my name, agreeably to the direction of the committee.

This sum, together with those previously paid, makes a total of seventy guineas which remained in the treasurer's hands when the objects of the association were attained, and it was therefore dissolved,—and which was divided between the Medical Benevolent College and the Widows' and Orphans' Fund.

I am, &c.

T. HOLMES.

39, Curzon-street, May 1, 1858.

#### SUCCESSFUL CASE OF CÆSAREAN OPERATION, MOTHER AND CHILD SAVED.

LETTER FROM JAMES HAWKINS, Esq., OF NEWPORT.

[To the Editor of the Medical Times and Gazette.]

SIR,—I regret that the pressure of professional duties has prevented me from forwarding the accompanying report of an important case earlier:—

The patient, Matilda Tanner, was 20 years old, and four feet one inch high. Her mother states of her, that she had been "hurt in her birth." She made no effort to talk before her 5th, and could not speak distinctly until her 12th year. Her deciduous teeth did not appear until she was 8 years old; at this age, too, she made her first essay to walk with crutches, with which she could not dispense until she had attained the age of 10. She menstruated first in her 18th year, thence to the period of her confinement only four times, at irregular intervals, and in small quantities. From the age of 12 to 20 she enjoyed uninterrupted good health.

On the 17th of February, 1858, labour-pains commenced. I saw her next day, and upon examination per vaginam found that the dimensions of the pelvis were very irregular and small, the last lumbar vertebra projecting so far over the brim that the antero-posterior diameter, or rather the distance between the symphysis pubis and last lumbar vertebra did not exceed an inch and three-quarters. Expulsive pains not having commenced, I left her till next day. On the 18th I again visited her, in company with Messrs. Brewer and Woollett, both of whom coincided in opinion with me that the Cæsarean section was the most feasible, the only means whereby the life of the foetus could be preserved, and, under the circumstances, the most favourable to insure the life of the parent. Accordingly in their presence, and with my

Assistant, Mr. Charles M'Ardle, having previously obtained the consent of the patient and her parents, I proceeded to operate. The bowels had been frequently moved during the day, the bladder was emptied, and about a quarter of an hour before the operation the membranes had ruptured without interference, the os being dilated about the size of half-a-crown.

Having been placed on a table with her legs hanging over one end, and her head and shoulders slightly pillowed up, she was put under the influence of chloroform. I commenced an incision about half an inch to the left of, and the same distance below, the umbilicus, extending about eight inches towards the pubis, and parallel to the mesian line. Integuments and subcutaneous adipose tissue having been cut through, the subjacent tendinous structures and peritoneum were successively divided to the same extent as the first incision. The uterus being now exposed, was cut into to the extent of about six inches, bringing to view the fetus, presenting naturally with the funis coiled round it. The fetus, placenta, and membranes, having been carefully removed, the uterus contracted firmly almost immediately. A small portion of omentum that protruded having been returned, the parts were quickly brought together with sutures, and long strips of adhesive plaster in their intervals; over this were placed a few rolls of lint, and a broad bandage being tightly applied over all, she was removed to bed. No vessel required ligation, and there was very little hemorrhage during the operation.

The baby being detached from the placenta was consigned to the care of a female attendant, and when seven days old weighed 8½ lbs. After being conveyed to bed the patient was ordered to have one of the following powders, *R. Pulv. opii, gr. vj., Hydrarg. chloridi, gr. iij., M. in Pulv. iij., divide, unam tertius horis.* At 10 o'clock p.m., four hours after the operation, the pulse was 102. She had taken two of the powders, did not complain of pain, and had a slight discharge from the vagina.

20th, 2nd day of the operation.—Passed a restless night, but without pain; pulse 96. *R. Pulv. opii, gr. xij., Hydrarg. chloridi, gr. vj. M. in pil. vj. divide, unam 4tis horis.*

21st, 3rd day.—Slept five or six hours last night, and passed water for the first time; has occasional pain like uterine pain in the abdomen, which yields a tympanitic sound on percussion; pulse 94. In the evening of this day the uterine pain became more severe and frequent, and there was tenderness on pressure over the abdomen. She had pain in the head also, and an anxious countenance; there had been a slight bloody discharge from the vagina, which was very fetid; the pulse rose to 104. *R. Pulv. opii, Hydrarg. chloridi, aa gr. vj. M. in pil. vj. divide, unam quaque hora.*

22nd, 4th day.—Slept a little occasionally last night; tympanitis and abdominal tenderness rather increased; pulse 96, intermittent. In the evening the pulse was 130, small and wiry; the uterine pains recurred more frequently, and were the more distressing, owing to the tympanitis, which still continued, and the peritonitis, which had now supervened. A common enema was given. This was retained entire for two hours, after which the bowels began to act freely; to have *Pulv. doveri gr. viij.* at bed hour.

23rd.—Had no sleep last night, the gums tender, pulse 134; bowels moved frequently and involuntarily. Peritonitis and tympanitis still continue. *R. Etheris chlorici, spt. ammon. aromat. aa ʒij. tinct. cinchon. co. ʒss. aquae ʒiij. M. ʒss. quaque hora.* The uterine pain recurred in the afternoon; at night the pulse was reduced to 120. *R. Pulv. opii gr. xij., calomel gr. vj. M. in pil. vj. divide, unam secunda quaque hora.*

24th.—Slept a little last night, bowels still acting very freely; has a slight discharge from the vagina. Pulse 120, tympanitis much less, peritonitis easier. At 8 o'clock p.m. she was roused from sleep by a sudden noise, after which she grew fretful; the uterine pain recurred more severely, and the pulse rose to 132; ordered to continue the last pills, some of which remained, owing to her having slept a good deal this day, and of course was not awakened to take the pills.

25th, 7th day.—Had an easy night, tympanitis entirely gone, peritonitis almost gone, pulse 120. On this day the wound was opened, and the sutures removed, the upper part looked very healthy and inclined to adhere, and from the lower end there was a very offensive discharge. Having carefully sponged the wound, I placed a thin strip of lint spread

with ung. cetacei along its edges, and brought them closely together with long strips of adhesive plaster, placing a folded towel for a pad on each side; I bound a broad roller over all. After this the patient expressed herself much relieved, but fatigued; to have an ounce of brandy in arrowroot directly, and beef tea frequently. In the evening the pulse was 120; weak; she called for something to eat; the uterine pain had recurred, but not so severely. *R. Pulv. opii gr. vi. in pulv. iij., one to be taken should pain come on.*

26th.—Had a very good night, bowels quiet and very little pain; pulse 106; feels comfortable and hopeful. In the evening the pain recurred as usual. Repeat the last powders.

From this date she continued to progress steadily, with the exception of a troublesome attack of bronchitis, which yielded to appropriate treatment. The wound was dressed every other day with a strip of lint, adhesive plaster, compresses, and roller as before, saturating the lint with the tinct. benzoïn co. instead of spreading the ung. cetacei over it as in the first dressing, and stimulating the edges occasionally with a strong solution of nitrate of silver. The uterine pain continued to occur in the afternoon, but becoming less, and coming on at a later period each day for a week after this date, when it disappeared entirely. It was always much assuaged by two grain doses of the pulvis opii, of which she had one each afternoon.

On the 18th of March she had a slight show of the menstrual discharge. On the 25th she began to apply the baby to the breast, and in a few days after had a fair supply of milk for it. The cicatrix of the wound measures at present only four inches.

For the first week the patient was kept entirely on milk and farinaceous food, after which she had beef tea, and in a few days was allowed a small quantity of mutton daily. On the 4th of April she got out of bed for the first time. Since then she and the baby, a fine little girl, have frequently been in my surgery, and are at present in perfect health.

I am, &c.

JAMES HAWKINS.

Newport, Monmouthshire, May 3, 1858.

## REPORTS OF SOCIETIES.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, APRIL 27, 1858.

Mr. FERGUSON in the Chair.

A paper was read by Mr. SWERING on

A CASE OF LACERATION OF THE INTESTINE (ILIUM), UNACCOMPANIED WITH EVIDENCE OF EXTERNAL LOCAL INJURY, OR OF INTERNAL DISEASE.

A healthy young man was thrown from the front of an empty waggon, on which he was riding, and fell on a heap of small stones by the road side. Getting up, he felt a little shaken, with some pain on the left hip and right shoulder, which parts were found to be bruised and discoloured on the following day. He walked some distance after the fall, and performed part of his duty in attendance upon his horses. He complained of great uneasiness through the next twenty-four hours, with costiveness, and a constant desire to have a motion without the power to relieve himself; but he had no symptoms of collapse, nor even nausea. He retained food and several doses of medicine, etc. He expired suddenly, after the administration of an enema, on the second day after the accident. On post-mortem examination, a circular wound in the ilium, about an inch in diameter, was found. There was no bloody effusion in the peritoneal cavity. There had been no symptoms indicating peritonitis during life, but there was lymph effused on its surface, and the eversion of the edges of the wounds proved the infliction of the injury during life. The intestines were quite empty.

The CHAIRMAN, in inviting discussion on the subject, said the absence of pain appeared to him one of the most remarkable features in the case.

Dr. MARKHAM said, the intestines had been injured in

several other places besides the point of rupture; inflammation appeared to exist over the whole of the intestine, and the place where the rupture occurred was no doubt originally in a similar condition. The rupture, he believed, must have taken place when the patient went to stool.

Dr. JENNER said he had seen several cases of perforation of the intestine unaccompanied by pain, while in others he had known the pain to be so intense that the patients screamed violently from the suffering they endured.

Mr. SPENCER WELLS said the author appeared to lay much stress upon the fact that there were no external marks of injury. He (Mr. Wells) did not think that circumstance one of very rare occurrence. He had himself seen several cases of severe internal injury (among them two cases of rupture of the bladder from falls), in which there was no external manifestation whatever.

A paper by Dr. MURCHISON was then read on

#### CONTRIBUTIONS TO THE ETIOLOGY OF CONTINUED FEVER; OR AN INVESTIGATION OF VARIOUS CAUSES WHICH INFLUENCE THE PREVALENCE AND MORTALITY OF ITS DIFFERENT FORMS.

The subject of this paper was an investigation into the various causes which influence the prevalence and mortality of the different forms of continued fever. The materials consisted principally of an analysis of 6628 cases of continued fever which had been admitted into the London Fever Hospital in the ten years during which the distinctions had been recorded between typhus, typhoid, relapsing fever, and febricula. The results thus arrived at were compared with the statistical data which the author had obtained from many of the principal hospitals in England, Scotland, and Ireland, and from various published records. The subject was discussed under the following heads:—

##### A. Prevalence of Continued Fever.

I. The various epidemics of continued fever which have prevailed in Great Britain and Ireland during the present century.

II. Which are the forms of continued fever of which these great epidemics have been composed?

III. The influence of months and seasons of the year on the prevalence of the different forms of continued fever.

IV. The influence of sex.

V. The influence of age, as shown by a calculation of the mean age of each of the different forms of fever, and by ascertaining the number of cases in each quinquennial period of life.

VI. The influence of occupation and station in life on the prevalence of the different forms of fever.

VII. The localities of London in which each form of fever is most prevalent, as shown by the localities from which the 6628 cases admitted into the London Fever Hospital had been derived.

VIII. Over-crowding, with deficient ventilation, and destitution, as causes of fever.

IX. Putrid emanations from decomposing organic matter in drains, cesspools, churchyards, etc., and organic impurities in drinking-water.

X. The contagiousness of the different forms of fever.

XI. The influence of recency of residence in large towns as a predisposing cause of fever.

##### B. Mortality from Continued Fever.

I. The rate of mortality from fever in the London Fever Hospital, as compared with that of eleven other hospitals.

II. The rate of mortality in the different forms of fever.

III. The influence of months and seasons of the year on the mortality of the different forms of fever.

IV. The influence of sex.

V. The influence of age.

VI. The influence of station in life.

VII. The influence of recency of residence in large towns.

The paper terminated with the following conclusions:—

1. Typhus and relapsing fever occur at irregular intervals, and often simultaneously, as wide-spread epidemics. They then gradually disappear, and both of them, but especially the latter, may be absent for years from those places where, during the epidemics, they are usually the most prevalent.

2. Typhoid fever does not occur in such wide-spread

epidemics. In certain places it is never absent, and its prevalence varies but little from year to year. When outbreaks of it occur in other situations, these are always of the most local and circumscribed character.

3. Typhus and relapsing fever are quite independent of the season of the year; whereas typhoid fever is almost invariably most prevalent during the autumn, and it has been observed to be especially prevalent in seasons remarkable for their high temperature.

4. Sex has no influence over the prevalence of continued fever, nor over that of any of its forms.

5. Typhoid fever is pre-eminently a disease of childhood and adolescence, at which periods of life we know that there is a marked proneness to enteric affections. Less than one-seventh of the cases of typhoid fever are above 30 years of age. Typhus and relapsing fever exhibit no such predilection for youth. Of typhus, one-half, and of relapsing fever, one-third, of the cases are above 30.

6. Typhus and relapsing fever are the appanage of poverty and destitution, and seldom or never occur amongst the wealthy, except from direct contagion. Typhoid fever attacks both poor and rich without distinction.

7. In large cities, typhus and relapsing fever are for the most part limited to those localities remarkable for the over-crowding of their inhabitants; and in country districts they are seldom or never met with, except when directly imported. Typhoid, on the other hand, occurs alike in the centre and suburbs of cities, in the crowded hovels of the poor, and in the spacious mansions of the rich, and also in isolated houses and hamlets in the country, without any traceable sources of contagion.

8. When fever breaks out in a house or locality, it seldom or never happens that some of the cases are typhus and others typhoid; but typhus and relapsing fever occur not unfrequently together.

9. Cases of what has been called "febricula" may co-exist along with any of the three other forms, but especially with typhus and relapsing fever. Most of them are either mild varieties of some of these, or dependent upon some derangement of digestion, or other non-specific causes.

10. Over-crowding and destitution appear to be the essential causes of typhus and relapsing fever, and to be capable of generating them *de novo*; while there is no evidence that they have any such influence over the production of typhoid fever.

11. There are many circumstances which tend to the belief that the emanations from decaying organic matter, or organic impurities in drinking water, or both of these causes combined, are capable of generating typhoid fever; but there is no authenticated evidence whatever to prove that such causes can give rise to typhus or relapsing fever.

12. There are some grounds for believing that a combination of the causes mentioned in the last two paragraphs may occasionally, although very rarely, generate a disease intermediate in its character between typhus and typhoid, or may (to speak perhaps more correctly) cause typhoid fever to assume some of the characters of typhus; but such cases cannot be used as an argument in favour of the identity of the poisons of the two diseases, for, first, instances are not wanting of two of the exanthemata co-existing in the same individual; and, secondly, if a known poison generates one train of symptoms, and a second poison another, a combination of the two poisons will generate a combination of the two trains of symptoms, without its being warrantable to conclude that the poisons in the first two instances were identical.

13. Typhus is eminently contagious. Typhoid fever is also contagious, but in a more limited degree, and possibly through a different medium. Again, typhus has in no instance been proved to communicate typhoid, nor typhoid to communicate typhus. An attack of either confers an immunity from future attacks of itself, but not of the other.

14. Recency of residence increases the liability to typhoid; scarcely, if at all, that to typhus.

15. The great majority of the cases of relapsing fever have been Irish, and of these a large proportion had but recently arrived in London. There seems reason for believing that fever imported from Ireland as "relapsing" may gradually pass into typhus.

16. Relapsing fever offers a marked contrast to typhus and typhoid in the small mortality which it occasions.

17. In comparing the mortality from continued fever at different times and places, it is essential to take into consideration the form of fever which has prevailed. If this be not done, the comparison is valueless.

18. The small mortality from continued fever constantly observed in Ireland, along with other circumstances, renders it probable that in that country a fever more or less allied to the relapsing, or to febricula, is more common than in Britain.

19. Season of the year has no influence over the mortality of any of the forms of fever.

20. In all of the fevers there is not much difference in the mortality of the two sexes.

21. Typhus is least fatal between the ages of ten and twenty, the mortality at that period of life being under 5 per cent. Above twenty, the mortality increases with the age, until of those above fifty considerably more than one-half die. The mortality from relapsing fever appears to be influenced by age in a similar manner. In typhoid fever, on the other hand, in no period of life is the mortality under 12½ per cent.; and although, as in typhus, the rate of mortality increases with the age, it does so in a less degree.

22. The mortality from typhus is greater among the very poor than among those in better circumstances. Typhoid fever is equally mortal in all classes.

23. Recency of residence increases the mortality from, as well as the liability to, typhoid fever, but has no such influence upon typhus.

24. Typhus and relapsing fever are strongly assimilated in the causes which give rise to them, if the specific poison of the two be not actually the same. Typhoid fever, on the contrary, appears to be a perfectly distinct affection, dependent upon totally different causes.

25. The facts which have been adduced in reference to the mode of origin of the different forms of fever deserve the serious attention of those entrusted with the care of the public health, for it is manifest, that should they be confirmed by subsequent observation, they must have an important bearing on the subject of hygiene.

Dr. WARDELL said that some years ago he took some elaborate statistics of 1200 cases of fever in Edinburgh, and his own conclusions drawn therefrom coincided with many of those mentioned by the author. The disease occurred almost invariably amongst the poor, and was chiefly confined to the old town, prevailing most extensively in the densely-populated districts, especially in the high "flats," which were inhabited by persons in the lowest stage of poverty. As to the generation of the fever, his conclusions did not quite coincide with those of the author, who appeared to regard the disease as chiefly generated by noxious emanations. In the Canongate and Cowgate, however, of Edinburgh, those who lived in the lower storeys, nearest the sinks and cesspools, were better circumstanced than those above them, who were in more destitute circumstances.

Dr. STALLARD confirmed some of the conclusions of the author by his own experience in Leicester. He agreed with him in believing that typhoid fever was more prevalent in autumn than in any other season. In a Hospital with which he had been connected the cases of typhoid fever averaged twenty or thirty in the autumn, and only five or six in the spring. In the epidemic of 1846 a large number of cases occurred among the better classes. He concurred in the opinion expressed by the author as to the causes of fever. In the years immediately preceding 1846, there was great destitution in Leicester, 10,000 persons being sometimes on the pauper list, yet there was no considerable amount of typhoid fever prevailing. In 1846, however, when the epidemic broke out, the trade of the town was not so depressed, and no great amount of destitution prevailed. A large portion of the town was only drained by surface drainage, and many of the poor lived in houses back to back, in the form of squares, with cesspools in the centre. In a street in the high part of the town typhoid fever prevailed for a considerable time, and it could not be accounted for till a sewer was found to be so choked up with rubbish that it was inefficient for drainage purposes. In a manufacturing village in Leicestershire, containing 2000 or 3000 inhabitants, a gentleman last year opened a cesspool, and spread the contents over a field in the centre of the village. The result was that 150 persons were ill at the same time, and a very large number of deaths occurred. He had observed that the number of cases of fever decreased with

the increase of the velocity of the wind—a circumstance that had an important bearing on the subject of ventilation.

Dr. JENNER remarked on the lamentable circumstances of so many persons dying annually from preventable causes. He had no doubt that typhoid fever arose from imperfect sanitary conditions. When it occurred among the rich it was among those who were exposed to faecal and other noxious emanations, or who drank water into which faecal matter had passed. Except among Medical men, he had only seen two or three cases of typhoid fever among the better classes of society.

Dr. GAIRDNER (Edinburgh) agreed with the author as to the essential difference between the poisons of typhus and typhoid fever. Typhus prevailed greatly in Edinburgh; but two years ago, six weeks or two months would sometimes elapse without a case being received into the Infirmary. While typhus, however, was disappearing, typhoid fever maintained its level, if it had not absolutely increased. He could not agree with the author as to the identity of typhus and relapsing fever. The experience in Edinburgh in 1843 rather tended to show that the poisons were essentially different, and generated under different circumstances. The type of typhus fever appeared to have changed during the last ten years. In the first place, it was a much milder disease than formerly. The mortality attending it ten years ago was not much less than one in four; but during the last three or four months he (Dr. Gairdner) had had fourteen cases of true eruptive typhus, not one of which had been fatal; and the average mortality was perhaps not more than one in twenty. The duration of the fever was also diminished. Ten years ago it never stopped before the fourteenth day; but now it was common to see it stop by the tenth day, and sometimes it ceased as early as the ninth or eighth day. All the symptoms were earlier in their development, particularly the eruption, which formerly did not appear before the beginning of the second week, but which now manifested itself by the sixth or fifth day, and he had seen it as early as the third or fourth. He had observed that eruptive cases, even though there might be an early crisis, did not relapse.

Dr. WARDELL differed from some of the conclusions of Dr. Gairdner. He had seen patients with true spotted typhus subsequently attacked with relapsing fever; but he considered the two diseases as distinct from each other as measles and small-pox.

Dr. JENNER said, he had long taught, from observations made ten years ago, that the eruption of typhus fever might be expected on the fifth day. For himself, he had not observed any change in the type of the disease during the last ten years.

Dr. GAIRDNER said, he only referred in his remarks to the disease as prevalent in Edinburgh.

Dr. STEWART said, he had years ago seen cases of typhus in Edinburgh answering the description given by Dr. Gairdner of the present form of the disease.

The Society then adjourned.

## MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at the meeting of the Court of Examiners on the 30th ult. :—

CHALK, FREDERICK MURRAY, Army.  
DANIEL, THOMAS PALMER, Beamister, Dorset.  
GILLINGHAM, CHARLES FREDERICK, Salisbury.  
IRVING, JAMES, Long Benington/Lincolnshire.  
JONES, MESSRS. RICHARD, Carnarvon.  
KNIGHT, HENRY JOHN, Sheffield.  
LOCKE, GEORGE WILLIAM, Royal Navy.  
MARRIOTT, CHARLES HAYES, Kebworth, Leicestershire.  
NISHET, ALFRED CALLAWAY, Clement's-inn.  
TURNLEY, GEORGE WASHINGTON, Tasmania.  
WALKER, ARTHUR, De Noe, Upper Berkeley-street, Portman-square.

At the same meeting of the Court Messrs. Clark Armstone Duckett, of her Majesty's ship Agamemnon, passed his examination as Naval Surgeon, and George Bellamy, as Assistant-Surgeon. The former gentleman had previously been admitted

a member of the College, his diploma bearing date July 28, 1852.

Also, on May 3.

ALSTON, WILLIAM EVELYN, Studland, Dorsetshire.

ALBERT, WILLIAM JOHN, Nassau, New Providence, West Indies.

ADAMS, SAMUEL HOPKINS, Bedfordshire.

CARDEN, HENRY WILLIAM, Cheltenham.

DANN, HENRY TALBOT, Fermoy, Co. Cork.

FOSTER, EDWARD, Romney.

GUY, WILLIAM, Maidstone, Kent.

HIND, JOHN MARRIOTT, Gonalston, Nottinghamshire.

LAWRENCE, CHARLES ALEXANDER, Ipswich.

NISLETT, FRANCES DOBBINGSON, Hackney.

PERCIVAL, WILLIAM, Richmond, Surrey.

PARSONS, FRANCES, Taunton, Somersetshire.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, April 29, 1858:—

ARCHER, LEWIS HITCHINS, London.

BARTLET, ALEXANDER EDWARD, Ipswich.

CLARKSON, FREDERICK, Whitby.

GRAY, JOHN TEMPERLEY, Hexham, Northumberland.

GROVES, WILLIAM GEORGE, Maidencombe, Devon.

MOORE, JOHN DANIEL, Leicester.

OSBORN, CHARLES, Bognor.

#### DEATHS.

ARNOTT.—March 7th, in the Warren Country, Africa, D. Ogilvy Arnott, late of Edinburgh, aged 35.

HARRISON.—On the 24th ult., Robert Harrison, M.D., F.R.C.S.L., Professor of Anatomy in Trinity College, Dublin.

LLOYD.—March 7th, at Bras River, West Coast of Africa. Edward Lloyd, son of Mr. William Lloyd, of Liverpool.

MARESKA.—Monsieur Mareeka, one of the most scientific scholars of the day, and for the last twenty-eight years Professor of Chemistry in the University of Ghent, recently died in that town. He was one of the principal and most active workers at the new Belgian Pharmacopœia. His works on organic and inorganic chemistry have been translated into German, and are extensively studied on the continent.

MAUTHNER.—Professor Mauthner, Ritter v. Mauthstein, Director of the St. Anne's Children's Hospital, Vienna, and a principal contributor to the *Journal für Kinderkrankheiten*, has just died of meningitis, in the prime of life.

MITCHELL.—On the 22nd ult., in Edinburgh, James Mitchell, R.N.

MULLER.—On Wednesday, the 28th ult., died at Berlin, Johannes Müller, M.D., Professor of Physiology and Anatomy. He was in his usual good health even two hours before his death, which occurred suddenly whilst asleep. He was to have commenced his summer course of lectures on Monday, May 3rd.

PLATTNER.—Professor Plattner, the celebrated writer on the blow-pipe, died at Freiberg early in the present year.

WILSON.—April 26th, at the Grove, Shropshire, E. Wilson, M.D. Edin. 1825, of Newcastle, and a magistrate of Staffordshire.

WRIXON.—On the 3rd inst., at 10, Belgrave-street, Argyle-square, Charles Wrixon.

The following names appear in the Medical Monthly Obituary, viz.—

J. Verling, M.D., half-pay Royal Artillery; Sir James Fellowes, M.D., half-pay. Surgeons.—W. T. Hoskin, M.D., 31st Foot; Robert Shean, half-pay, 7th Foot. Assistant-Surgeon.—J. Cruice, 84th Foot.

**ALCOHOL AND FOOD.**—Liebig tells us that, in temperance families, where beer was withheld and money given in compensation, it was soon found that the monthly consumption of bread was so strikingly increased, that the beer was twice paid for, once in money and a second time in bread.

He also reports the experience of the landlord of the Hotel de Russie at Frankfort during the peace congress; the members of this congress were mostly teetotalers, and a regular deficiency was observed every day in certain dishes, especially in farinaceous dishes, puddings, &c. So unheard of a deficiency, in an establishment where for years the amount of dishes for a given number of persons had so well been known, excited the landlord's astonishment. It was found that men made up in pudding what they neglected in wine. Every one knows how little the drunkard eats; to him alcohol replaces a given amount of food.—*Blackwood*.

**THE APPOINTMENT OF DR. A. TAYLOR AS AN EXAMINER AT THE ROYAL COLLEGE OF VETERINARY SURGEONS.**—"Dr. Babington has resigned the seat which he has so long and so ably filled at the Board of Examiners. The name of Babington has been associated with the onward progress of veterinary science, from the earliest days of its emancipation from the thralldom of ignorance and empiricism,—and hence we could have wished to have seen it still attached to the diploma of the newly graduated Veterinary Surgeon. If, however, this gratification is to be denied us, we have the pleasure to find that the loss is to be supplied by that of Dr. Alfred Taylor, of Guy's Hospital. In commendation of Dr. Taylor it is unnecessary we should say anything, and especially when we read in the columns of the *Medical Times*, that 'The appointment of Dr. Alfred Taylor to the examinership in chemistry in the Medical department of the University of London, will tend to raise still higher the character of this body. It must be highly satisfactory to Dr. Taylor to have obtained the post after competition with two highly-qualified men, while these gentlemen will not consider it any disparagement that a chemist who has earned by his works so high a reputation in all quarters of the world should have obtained the appointment.'—*The Veterinarian*.

**ROYAL ORTHOPÆDIC HOSPITAL.**—The eighteenth anniversary of this charity was celebrated last week, at the Freemason's Tavern, the Duke of Wellington in the chair. The claims of the Hospital were briefly set forth by the noble chairman, and it appeared from his statement, and the published report of the committee, that the number of patients admitted during the year was 1580, and the total number benefited since the opening of the Hospital nearly 23,000. The income for the year amounted to £2660, considerably exceeding the ordinary receipts in any previous year; but the extension of the wards, and the addition to the number of inmates, had greatly increased the exigencies of the charity. The aggregate receipts did not equal the augmented expenditure, and for the redemption of the mortgage debt of £6000 (the interest upon which entails an annual charge of £300), no provision whatever had yet been made. The necessity for enabling the committee to liquidate the mortgage, and thus relieve the Hospital from this heavy annual payment, was enlarged upon in the course of the evening, and it was pointed out that the income from annual subscriptions alone, ought to be made to cover the annual expenditure, leaving the receipts on such occasions as the present to be applied to the extension of the benefits of the Hospital. The subscriptions announced during the evening amounted to upwards of £1600, including 30 guineas from the chairman.

**GROSVENOR-PLACE SCHOOL OF MEDICINE.**—The distribution of prizes at this school took place on May 3rd; Robert Chambers, Esq., occupied the chair. The large room of the school was crowded, a great number of ladies being present. The prizemen were as follow:—Lord Mayor's Prize, presented by Mr. Alderman Salomons, microscope, value £10 10s., to Mr. A. Bannister. School Gold Medal for General Proficiency: Senior, Mr. E. Davies; Junior, Mr. H. Dow. General Anatomy and Physiology: First Senior, Mr. T. O. Mayor; Certificate, Mr. G. Phillips; First Second Year, Mr. E. Davies; Second ditto, Mr. E. Bucknill and Mr. H. Bucknill; First Junior, Mr. H. Dow. Surgery: First Prize, Mr. Phillips; Certificates, Mr. Godrich and Mr. Davies. Comparative Anatomy: First, Mr. T. O. Mayor. Practice of Medicine: Mr. Davies, Mr. Page, and Mr. Mayor, equal. Botany: First Prize, Mr. T. O. Mayor. Chemistry: First Prize, Mr. H. Dow. Practical Chemistry: First Prize, Mr. E. Cook. Materia Medica: First Prize, Mr. E. Davies; Certificate, Mr. E. Bucknill. Midwifery: First Senior Prize, Mr. Lomas; First Junior, Mr. Lovegrove; 1st Certificate, Mr. Phillips; 2nd ditto, Mr. Davies. For best paper read

before the Grosvenor-place School Medical Society: Mr. Lomas. Previous to the distribution of the prizes, the Secretary read his report, which showed that the school was in a satisfactory condition. The staff of lecturers had been made most complete; there were special lectures delivered in the school on histology, military surgery, comparative anatomy, and hygienic medicine; next session a short course of lectures is to be delivered by Dr. Henry, on the History of Medicine. The report further conveyed the expression of an opinion in favour of the proposed new plan of leaving the education of the Medical student in his own hands, and of basing the test of qualification solely on a sound and practical examination. After the distribution, Mr. Chambers delivered a simply eloquent and admirable address to the students, which was warmly applauded. Reviewing the progress of Medical art in these days, he dwelt with much force on the necessity which existed for each student to be prepared to cast away much of the old dogmatism of Physic, and to endeavour to rationalise his science to the fullest possible extent, by the pursuits of physiology, chemistry, and the other sciences on which Medicine should be based. At the same time he warned them against falling into the temptation of linking themselves with the prevalent and fashionable heresies. In no feeble terms he condemned quackery in every shape, and expressed his belief that in the end, and during the great progression of the intellect which now obtains, quackery would soon be easily detected by all, in all its deceit and pretension. In the evening the lecturers, pupils, and friends of the school dined together at the Freemasons' Tavern, and spent a most pleasant evening. Dr. McWilliam returned thanks for "The Navy" in an eloquent speech; and "Prosperity to the Sister Schools" was proposed, with much good feeling, by Dr. Thudichum, and acknowledged as warmly by Mr. Ernest Hart.

## VITAL STATISTICS OF LONDON.

Week ending Saturday, May 1, 1858.

### BIRTHS.

Births of Boys, 851; Girls, 866; Total, 1717.  
Average of 10 corresponding weeks, 1848-57, 1612.

### DEATHS.

	Males.	Females.	Total.
Deaths during the week ... ..	618	507	1125
Average of the ten years 1848-57 ...	532.1	512.5	1044.6
Average corrected to increased population ...	...	..	1149
Deaths of people above 90 ... ..	...	4	4
Deaths in 15 General Hospitals ... ..	38	17	55

## DEATHS IN SUB-DISTRICTS FROM EPIDEMICS.

	Population. 1851.	Small-pox.	Measles.	Scarlatina.	Hoop- ing- Cough.	Dia- rrhoea.	Ty- phus.
West ....	376,427	1	5	5	12	3	4
North ....	490,396	..	8	7	15	3	5
Central ..	393,256	..	9	2	10	2	8
East ....	486,522	..	13	7	11	1	8
South ....	616,635	1	19	11	21	2	6

REMARKABLE CASES IN THE RETURN.—A grocer, aged 26 years, died in consequence of having swallowed false teeth during his sleep, which produced hemorrhage from the stomach; a painter died of colica pictonum; a woman died after delivery by the Cæsarean operation; and a young soldier in the University College Hospital from a gunshot wound he had received at the storming of the Redan. The names of four nonagenarians, all widows, were inscribed in the Registers, the oldest of whom died at 6, Boot-street, Hoxton Old Town, at the age of 98 years.

## METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer ... ..	29.566 in
Mean temperature ... ..	47.1
Highest point of thermometer ... ..	65.0
Lowest point of thermometer ... ..	36.5
Mean dew-point temperature ... ..	41.5
Whole amount of rain in the week ... ..	0.84 in.
Amount of horizontal movement of air in the week ...	505 miles

## TO CORRESPONDENTS.

Dr. CONOLLY's sixth paper will appear next week with an Illustration of Senile Dementia.

Mr. Crosse.—The report shall appear next week, if possible.

A Medical Student.—Etügel is the best German and English Dictionary.

Mr. Crookery's cases shall appear.

William.—Pereira's Materia Medica.

Mr. Rhind.—The paper arrived safely.

Mr. Copney's note arrived last week after the publication of the *Medical Times and Gazette*.

Mr. Paget's paper, "On the Diagnosis and Treatment of Ulcers of the Tongue," will appear next week.

Ammonia.—A hint has been given to the gentleman in accordance with our correspondent's feelings.

Mr. Harris.—We do not see that any good would be done by publishing the letter.

Mr. Wale, Woodstock, Canada West.—Thanks for the specimens. The method of plugging the nares proposed, will be found described in the article "Epistaxis" in the *Cyclopaedia of Practical Surgery*.

Doubtful.—Dr. Hall and Mr. Smithard state, after very extensive acquaintance with teetotalers, that it is not true to say they are addicted to the use of opium.

A Wine-bibber should try the effect of a drop or two of acetic ether or butyric ether in a bottle of wine, and he will then know as much of the effect on the tongue as we can tell him.

Mr. West.—The Registrar General says—"As a general rule the mortality is highest in cold winters, lowest in winters of moderate temperature, and it has a tendency to rise when the temperature of the winter quarter exceeds forty degrees of Fahrenheit."

Verax Secundus.—We do not wish to discuss the "Principles of Homoeopathy." The question to be decided is whether Physicians and Surgeons, who do not profess those principles, are to attend patients with those who do.

Letters and papers are in type from Dr. Heslop, Birmingham, Dr. Elliotson, Mr. Newman, Dr. Whitehead, Dr. Mackay, Mr. Burne, Mr. Maysmor, Mr. Clough, with reports of Dr. Lankester's Lectures at the Royal Institution, and reports of the Norwich Pathological and North London Medical Societies.

**MR. WORTHY'S NEW FOMENTING APPARATUS.**

This apparatus is calculated to be useful, as it affords means of throwing a number of small jets of steam upon any part of the body, and of steaming flannels for fomentation.

**ERRATA.**—DR. BENGE JONES ON DIABETES MELLITUS.—In the 2nd table giving the variations of the sugar in the urine when sugar was taken with the food on the 7th, 8th, and 9th days, eight ounces of sugar are given. The text states that no sugar was taken. The table should be:—

		Weight.	Quantity of water.	Sugar in 24 hours.	Fluids taken.	Bread.	Sugar.
		st. lbs.	pints.	Sp. gr.	grains.	pints.	oz.
8th day	violent diarrhoea	5 4	5	1042	3800	8	7 1/2
7th "	" no diarrhoea	5 3 1/2	5 1/2	1042	4130	8	5 none
8th "	"	5 6	5	1042	3600	8	7 0
9th "	"	5 6 1/2	5	1043	3600	8	7 0
10th "	"	5 8 1/2	7	1040	5180	3	7 8

**ROYAL MEDICAL BENEVOLENT COLLEGE.****TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.**

SIR,—The following circular has been issued by the Treasurer of the Royal Medical Benevolent College with reference to the approaching Annual General Meeting:

"New Cavendish-street, 1st May, 1858.  
"My dear Sir,—If you value the Institution I have laboured so hard to establish for the benefit and comfort of my poorer brethren, their Widows and Orphans, and which you have so nobly assisted to place in its present prosperous position, you will not, I hope, fail to be present at the 'Annual Meeting' on the 11th inst., at the Freemason's Tavern, at 3 o'clock, to support the council, and yours ever,

Most faithfully,

"JOHN PROPERT."

"Pray bring your friends!"

Is it probable that any business which may be deemed for the interests of the Medical Benevolent College will be calmly considered by a meeting under the influence of such a personal appeal? Mr. Propert is entitled to the greatest regard and admiration for the energy and untiring zeal he has shown in projecting and working into life this institution; but, surely it is, to say the least, very unusual conduct on the part of a public officer of a charity thus to endeavour to prejudice an important meeting of its governors, and thereby influence the election of councillors.

I trust that the governors will indeed attend the meeting, but that they will do so unbiassed by Mr. Propert's appeal.

May 4, 1858.

I am, &c.

WM. CHOLMELEY.

DEPUTATION FROM THE MEDICAL CORPORATIONS OF ENGLAND TO THE EARL OF DERBY.

**TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.**

SIR,—In the report which has appeared in the daily papers of the deputation from the Medical Corporations of England to Lord Derby, on the 27th inst., the name of Dr. O'Connor is introduced. I am directed to inform you that that gentleman was not a member of the deputation, nor had he been invited to accompany it.

Royal College of Physicians, April 29, 1858.

I am, &c. W. COPNEY, Secretary.

With reference to the above letter we have received the following explanation from Dr. O'Connor:—

"SIR,—Having seen a letter published from the College of Physicians in which it is stated that I was not a member of the deputation from the Medical Corporation to Lord Derby, on the 27th inst., and that I had not been invited to accompany it, I wish to give the following explanation. First of all, I must observe that I have not seen any statement to the effect that I was a member of the deputation. That I accompanied it is quite correct, although I had no invitation from any of its members; but some days before a communication was made to me by a supporter of Mr. Headlam's bill, to the effect that Lord Derby had appointed the Tuesday following to receive the deputation, and, at the same time, a wish was expressed that I should accompany it. I stated, in reply, that I would call on a gentleman who I supposed would be a member of the deputation, and if it was desired that I should do so I would comply. My time did not admit of calling on him at the hour most likely to see him, and on Tuesday, at some inconvenience, I went to Downing-street, and seeing from the list of those waiting on Lord Derby, that there was another gentleman present not of the deputation, nor connected with it, I entered the room. I supposed, from this fact, that on the day preceding that on which the delegates from the corporations of the United Kingdom had an interview with Mr. Walpole, I was requested by one of those gentlemen to be present at that interview, and, having been requested last year by gentlemen connected with the College of Physicians to attend the deputation to Lord Palmerston, my presence at Downing-street on the 27th inst. was equally desirable. However, whether it was or not, I now feel that I have rendered good service to the cause of Medical Reform, for had it not been for me, the Profession would be altogether ignorant of what passed between Lord Derby and the members of the deputation; and, as you, sir, can bear testimony, the only correct report was supplied by me for your pages. That my labours on a former occasion were appreciated, is proved by the fact that the representatives of the College of Physicians individually thanked me for those labours, and the representatives of the Dublin Medical Corporations placed the following on record in your pages:

"Conference of the Medical and Surgical Corporations.—Irish Department.

"To the Editor of the Medical Times and Gazette.

"Office, College of Surgeons, Dublin, June 23, 1857.

"Sir,—We beg leave to express through your pages our thanks to Dr. O'Connor for the full and accurate report of what passed at the interview with which the deputation from the different Medical Corporations of the United Kingdom were favoured by Lord Palmerston, on Tuesday, June 9, at Cambridge House, on the subject of the Medical Bills now before the House of Commons, and more especially as the representatives of the press were not permitted to be present. Had it not been for Dr.

O'Connor's promptitude and great labour on the occasion, no accurate report of what took place could have been known to the Profession.

"(Signed)

"J. Moore Neilgan, M.D., Representative of College of Physicians.  
"R. Harrison, Professor of Anatomy, F.R.C.S.  
"Hans Irvine, President, Royal College of Surgeons in Ireland."  
Medical Times and Gazette, July 4, 1857, p. 28.

I am, &c.

WILLIAM O'CONNOR, M.D.

Upper Montagu-street, W., May 6, 1858.

**CHLORODYNE.****TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.**

SIR,—I prepared the solution of "Chemicus" yesterday, and had some difficulty in getting the Hydrochlorate of Morphia to dissolve. At first I rubbed it in a mortar, with the united fluids and gingerine; but finding that I did not succeed in this way, I put all the ingredients into a bottle and kept it near the fire agitating occasionally, and at last succeeded in making the solution; but I found that, after standing for some time and becoming cool, the morphia was again precipitated. When the solution is dropped into water it sinks to the bottom, and will not unite with it unless a considerable quantity of mucilage be added. Will "Chemicus" be kind enough to state how he makes his solution, and whether precipitation takes place after it has stood any time.

Edinburgh, May 4, 1858.

I am, &c.

A SURGEON, R.N.

COMMUNICATIONS have been received from—

Dr. CONOLLY; Dr. BENGE JONES; Mr. PAGET; Dr. SYMONDS, Clifton; Dr. RANKING, Norwich; Dr. SIEVERING; Dr. LEARD; Dr. RICHARDSON; Dr. ROBERT LEE; Dr. GREENHALGH; Dr. GUY; Mr. BAKER BROWN; Dr. STALLARD; Dr. LANKESTER; Dr. H. SILVESTER; Mr. CROSKERY; Dr. CHOLMELEY; Dr. BARKER, Bedford; Mr. HOLMES; Mr. ROBERTSON, Manchester; Mr. CROSBIE, Norwich; Dr. S. SUTHERLAND; Dr. DYCK, Aberdeen; Mr. MAYMOR; REGISTRAR GENERAL; Mr. CROFT; Mr. GOWPERTZ; Mr. SYMES, Bridgewater; Mr. COPNEY; Mr. RIVERS; Mr. HAWKINS; Mr. CLOUGH; Mr. BARLOW; Mr. HUGHES; SECRETARY GENERAL BOARD OF HEALTH; Mr. GOULD; Mr. WORTLEY; Mr. SADLER; Mr. ADAMS; MESSRS. LEOGATT, HAYWARD and LEOGATT; PRESIDENT, VICE-PRESIDENT, and COUNCIL of the PHARMACEUTICAL SOCIETY; Mr. MASKELL; Dr. BAINES; Mr. ORRIDGE; Mr. GREENWOOD; Mr. F. HOLMAN; Mr. W. ROBERTSON; Mr. MILNER; Mr. J. EARLE; Mr. J. HAINES; Mr. S. BURMAN; Dr. TUCK; Mr. McDERMOTT; Mr. THOROLD; Mr. REIND; Mr. HARRIS; Mr. EVANS; Dr. ERHARD, Berlin; Dr. E. LEE; PRESIDENT and TREASURER of St. Thomas's Hospital.

**APPOINTMENTS FOR THE WEEK.**

May 8. Saturday (this day).

Operations at St. Bartholomew's, 1 1/2 p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m.; Charing-Cross, 1 p.m.

ROYAL COLLEGE OF SURGEONS, 4 p.m.: Professor Hewett, "On Tumours of the Head;" Professor Busk, "On the Invertebrata;" Professor Quekett, "On the Vertebrata."

ROYAL INSTITUTION, 3 p.m.: Edwin Lankester, M.D., F.R.S., F.L.S., "On the Vegetable Kingdom in its Relations to the Life of Man."

MEDICAL SOCIETY OF LONDON, 8 p.m.: Mr. V. de Meric, "On Gangrene and Phagedena in Specific Sores."

**10. Monday.**

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.; Orthopaedic Hospital, 2 p.m.

NORTH LONDON MEDICAL SOCIETY, 8 p.m.

**11. Tuesday.**

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

ROYAL COLLEGE OF SURGEONS, 4 p.m.: Professor Hewett, "On Tumours of the Head;" Professor Busk, "On the Invertebrata;" Professor Quekett, "On the Vertebrata."

ROYAL INSTITUTION, 3 p.m.: J. P. Lacaita, Esq., "On the History of Italy during the Middle Ages."

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8 1/2 p.m.: Mr. John Tudor, "On a Case of Excision of the Elbow;" Mr. Coulson, "On a Case of Hydatids in the Tibia;" Mr. Holmes Coote, "On the Treatment of Contracted Joints."

**12. Wednesday.**

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Orthopaedic Hospital, 2 p.m.

NORTH LONDON MEDICAL SOCIETY, 8 p.m.: Mr. Catlin, "On Some Peculiarities of the Antrum with reference to Surgical Practice."

**13. Thursday.**

Operations at St. George's, 1 p.m.; Middlesex, 1 1/2 p.m.; Central London Ophthalmic, 1 p.m.; London, 1 1/2 p.m.

ROYAL COLLEGE OF SURGEONS, 4 p.m.: Professor Hewett, "On Tumours of the Head;" Professor Busk, "On the Invertebrata;" Professor Quekett, "On the Vertebrata."

**14. Friday.**

Operations at the Moorfields Ophthalmic, 10 a.m.; Westminster Ophthalmic, 1 1/2 p.m.; Great Northern, 2 p.m.

ROYAL INSTITUTION, 8 1/2 p.m.: Henry Bradbury, Esq., "On Printing."

**EXPECTED OPERATIONS.**

King's College Hospital.—The following operations will take place this day (Saturday), at 2 o'clock:—

Lithotomy; lithotripsy. By Mr. Lec.

St. Mary's Hospital.—The following operation will take place on Wednesday next, at 1 o'clock:—

Vesico-vaginal fistula. By Mr. J. B. Brown.

Royal College of Physicians.

By JOHN ADDINGTON SYMONDS, M.D. F.R.S.E.

Consulting Physician to the Bristol General Hospital, &amp;c.

## ON HEADACHE.

## LECT. III.—Continued.

THE treatment of Neuralgic Headache scarcely needs special consideration, after what has been said of the treatment of nervous headache. It is sufficient to observe that this disorder is often of such severity and pertinacity as to require the boldest exhibition of remedies: full doses of opium or aconite at the time of pain, and large quantities of quinine or arsenic in the interval. These are the cases in which iron, and especially the carbonate, has so often answered well. I can also speak favourably, from experience, of large doses of muriate of ammonia. I ought not to omit to mention my sense of the great utility of aconitine ointment as a palliative. The endermic use of morphia, sprinkled on a blistered surface, has likewise been one of the most powerful of anodyne resources. On what principle relief is afforded by a ligature round the head, it may be difficult to explain; but the fact is undeniable, and the remedy of ancient repute. Shakspeare makes Prince Arthur say to Hubert,

"When your head did but ache,  
I knit my handkerchief about your brows,

And with my hand at midnight held your head," etc.

A benumbing influence is exercised on the superficial nerves; and this would seem to be reflected on the internal nerves, which are the seat of pain. I have in my own person felt temporary relief to neuralgic toothache by firm pressure of the cheek; and in this case it is unquestionable that the operation must be of a reflex nature. After all, I doubt if the action be more mysterious than that of sedatives applied externally; the mode of which action has been already discussed (a).

Our remarks on treatment have thus far had reference to the headache of congestion, and to that which is a purely nervous affection. There is a mixed form of headache, to which we adverted in a former lecture, and in which there are both these elements, usually with a predominance of one of them. These cases are most difficult to manage; for, while they require a certain amount of the measures suited to both kinds of disorder, it is very easy to go wrong by excess. In our anxiety to keep down vascular turgescence, we may be tempted to the use of remedies which, though they afford temporary relief, are almost sure to add to nervous irritability. Such are local depletion, blisters, and purgatives. Yet if the neurotic derangement seems uppermost, and we employ nerve tonics too freely, there is a risk of aggravating the vascular disorder. This, however, is the slighter risk, unless our remedies are very powerful. Every case will need a separate consideration, and an individuality of treatment. On the one hand, we may find that a few leeches or a blister to the nucha, or leeches to the hemorrhoidal vessels, or mustard pediluvia, or dry cupping along the spine or on the temples, with shower-baths, and cold sponging of the spine followed by diligent friction, and tepid or evaporating lotions to the forehead and scalp, with occasional aperients in the morning, diaphoretics at night, and a well regulated diet, will meet the congestive element without recourse to any of the more energetic antiphlogistic measures; and on the other hand, if we cannot apply to the heroic doses of quinine, we shall derive great assistance from zinc, especially the valerianate, as well as from most of the pure nervines. Of the reinforcers of nervous power, I have had reason to think well of the action of minute doses of strychnia and of nux vomica, when I could not apply to quinine or iron.

(a) My friend, Dr. Williams, whose opinion is of great weight in all questions of pathology, is inclined to refer the alleviation produced by external pressure in some kinds of headache to some operation exerted on the bloodvessels.

Phosphorus I have only employed in the form of phosphoric acid and of phosphate of iron, not without hints of advantage, but not with such signal good results as to make me dwell upon them. But I have been informed by others that they have attached great importance to this agent.

For the relief of present pain in these cases, anodynes must often be administered. Opium, or morphia combined with alteratives and salines, succeed with some; others are more profited by henbane, camphor, and Indian hemp, or by the extract of poppy.

*Treatment of Sympathetic Headache.*—If we were right in our conclusion that pain is rarely forced on the nerves of the head, that is, that it rarely occurs without some readiness of the nerves to ache when any offence is transmitted to them, it will be evident that the management of cases of this class, while it consists in warding off such causes of irritation as may come from distant organs, is equally concerned in lessening if not in removing the cerebral susceptibility also. The treatment of gastric headache will not be confined to the cure of dyspepsia, of whatever form, though this is the main object; for in diminishing the frequency of attacks dependent on gastric irritation, you are in one respect acting on the primary fault, because by diminishing the habit you allow the nerves time for growing into a less irritable condition, since frequent returns almost inevitably confirm the habit. But the correction of dyspepsia produces effects co-extensive with the whole economy, and therefore if a patient has by medicinal courses, or by regulation of diet, or by hygienic methods lost his dyspepsia, and with it his tendency to headache, it does not follow that he has merely put away the sympathetic origin of his complaint. He will from the same system of treatment, through the remote influence of improved digestion, have acquired healthier blood, and a sounder tone in his nervous system. Remarks of a similar bearing might be made on the influence of an improvement in the functions of the uterine system in patients whose cephalalgia has disappeared after such improvement, for in these cases also there is the positive advantage of amended general health, as well as the negative good belonging to the removal of a source of irritation. Still we have to bear in mind when reasoning upon such examples, that although the cerebral nerves may be so irritable as to derive sympathetic disturbance from any organ whose function is deranged, yet that the specially sympathetic headache implies a tendency to respond to irritation from one part more easily than from another. Given the same susceptibility of the nerves of the head, in one person it will only be provoked by gastric irritation, in another only by uterine. But independently of this occasional communication of disorders, there would appear to be sometimes established a permanent morbid consensus between the cephalic ganglia and the semilunar in the one case, and between the cephalic and the ilio-lumbar in the other. And so the subsidence of one will allow the other to subside also. It is not often, however, that of the three great ganglionic centres, two only suffer together, with exemption of the third. More frequently they are all more or less involved in the painful consequences of their alliance.

As to gastric headache, I have generally found that when an attack of this nature has been once set up in consequence of disorder of the stomach, it will take its course. Now and then a remedy may tell upon it, if employed at the very onset. Thus, as one of the most common causes of irritation is an excessive secretion of acid fluid, the patient has been directed to take a teaspoonful of carbonate of soda or magnesia, in a tumbler of water, with a teaspoonful of sal volatile, to which I have sometimes added a teaspoonful of common salt, with a view of assisting the stomach to eject its contents by vomiting, if so disposed. And sometimes this potion has stopped the pain by neutralizing the acid matter, and its impression on the gastric nerves. But more commonly it is the state of the membrane which gives birth to this secretion that is the source of irritation, and cool mucilaginous drinks with prussic acid and alkalies must be continued for some hours, with sinapisms to the epigastrium; for gastric dyspepsia is more commonly the cause of headache than atonic indigestion. But, whether it be the one or the other, the irritable nerves must be soothed; and this purpose is often magically answered by a cup of strong coffee. The preventive treatment of the dyspepsia I cannot, of course, undertake to discuss on this occasion; and I seem already to have said too much. For a like reason, I do not speak of duodenal indigestion, and its bilious headache. I will only mention as a contribution from

my experience of such cases, that long periods of exemption from returns of these headaches have occurred to patients who have faithfully observed my direction that they should drink a tumbler of common salt and water every morning an hour before breakfast; and that I have in other instances been led to assign great value to the use of pills of rhubarb, ox-gall, and nux vomica, at dinner-time.

The uterine headache has not in my hands received treatment very different from that which is applicable to neurotic headache in general. But of the anodynes for immediate relief I have perhaps oftener selected camphor and belladonna, and conjoined with them sinapisms to the sacrum, and the use of the hip-bath. A full dose of chloric ether or of chloroform has also acted very happily in these cases. Of course, the remedies must be varied according as the catamenial flow is defective or in excess.

*Treatment of Tizemic Headache.*—On that form of secondary headache which is an all but constant symptom of continued fever, it is obviously unnecessary to trouble you with any lengthened remarks. That although probably excited by the altered condition of blood which belongs to the fever, it is, in part, dependent on the congestion of the vessels, is indicated by the measures which relieve the pain. A cool pillow, removal of the hair, refrigerating lotions, leeches to the temples, and sinapisms to the nucha or epigastrium, so well known in the routine of fever treatment, are remedies for vascular congestion; yet they by no means displace the use of sedatives. Small doses of Dover's powder, or henbane, with a mercurial, are very helpful. And though so many of the efficient remedies are antiphlogistic, yet that the pain is not purely vascular, may be inferred from the fact that there is a natural tendency to its subsidence after a few days, and that had the vascular disorder been commensurate with the pain, worse results must have ensued, in the way of inflammatory exudation. In former times, the answer to this remark would have been that the delirium, hebetude, and sopor, which follow the headache, indicate such consequences of the prior congestion or sub-inflammation, but this, again, is contradicted by the negative results of post-mortem examinations in persons who have died at this period of the disorder. The disturbing action of the febrile poison was once brought prominently before me in the case of a woman who sank after violent maniacal excitement of five or six days' duration, and in whom I suspected typhoid fever, only because two or three others of the family had been seriously affected about the same time, and in the same house. A careful inspection of the brain detected nothing but turgescence of the membranes, but the follicles of the intestines were frightfully ulcerated, even at that early stage, and showed the intensity of the poisonous action in that part of the body coincident with a no less deleterious process in the brain, which however did not reveal itself in textural changes.

The secondary headache belonging to rheumatism requires that discrimination, to which I formerly alluded, of the pain which is merely a symptom of febrile movement, from that which depends on a profounder action of the blood-poison, whether on the dura mater or on the brain itself. And a like remark applies to acute gout.

Chronic rheumatic pain of the head may be often traced to cold, and may be cured by a warm nightcap, or by discontinuance of cold ablutions.

The headache of chronic gout I have found amenable to most of the remedies which are useful in the headaches which have not this complication. But colchicum often comes in with marvellous power. I am informed by Mr. Spencer Wells that having seen how great a control quinine exerts over this form of cephalalgia, he has been disposed to inquire whether its action bears any relation to some curious observations of Ranke on the diminution of uric acid in the urine of persons under its operation. As far as my own observation goes, I should incline to the belief that the cephalalgia of the gouty diathesis is not the direct product of a gouty poison, but only a neurotic disorder belonging to that state into which the nervous system has grown in these subjects, analogous to that which occurs in other derangements of the constitution. Were it excited by a chemical materies morbi, we might expect such changes in the intra-cranial fibrous tissues as we find in the joints where there have been actual deposits of gouty matter.

And I take the same view, *mutatis mutandis*, of the nervous or neuralgic headache consequent on the syphilitic constitution, and of its appropriate treatment.

If we try to sum up one or two practical conclusions, apart from such speculative discussions as I may have too much indulged in, I think it will be found that they are mainly these:—

1. That headache has an importance of its own; and that, whatever connexion there may be between this affection and the disorders of other parts of the body, the head itself is to have the chief consideration.

2. That headache, whether primary or sympathetic, considering the frequency of its occurrence, is rarely dependent on disorder involving danger, or serious impairment of the function of the brain.

3. That symptomatic headache, even when belonging to grave lesions, may be benefited by the treatment applied to the primary forms.

4. That the primary headache, whether caused by an original susceptibility in the ganglionic nerves of the brain or by a morbid sensibility resulting from previous disease or weakness, is to be relieved by sedatives, and to be cured by tonics and nervines. He will be the most successful practitioner who can best wield those two great weapons, Quinine and Arsenic.

5. There is a natural tendency in this disorder to decline with advancing life.

On comparing cephalalgia with pain in other parts, and with those forms of pain which bear most analogy to it, more especially in the paroxysmal character, and in the accompanying conditions and symptoms, I think it would be difficult to find any affection to compete with it either in frequency of occurrence or in the duration of the liability to attacks. Certainly we may exclude from such rivalry, angina pectoris, gastralgia, enteralgia, and neuralgia of the extremities. Toothache, as we have already observed, is too obviously related with structural changes to be put into the category. But there remains that pain, of which we hear so much in females—*dolor dorsi*. Ladies have been divided into two great classes: those who have a back, and those who have not—a sufficient indication of the frequency and chronicity of pain in this situation. It resembles headache in its mode of coming on and in its remote causes, and it resembles it equally in its pathology. Like headache, it may be related with structural changes, and with congestive or inflammatory states; or it may be purely nervous, and probably it is far more often of this kind; and as such, it may be dependent on original or acquired sensibility of the uterine and ovarian nerves, wrought upon by abnormal states of the function of those organs, or by disorders in other parts of the system. The sympathetic production of this pain, which makes so large a part of female misery, might be traced to radiation in the sensorial centres, or to transmission from ganglion to ganglion, in the same manner which was attempted in reference to the production of headache; and I believe that an energetic and persevering use of like remedies would be of equal use, and certainly might in many cases supersede the use of distressing local applications.

I will not enter upon the analogy of gastralgia, as it would occupy too much of our time; but I cannot forbear adverting for a few moments to sternalgia, commonly known as angina pectoris.

Far less frequent than headache, it is oftener associated with serious and perilous disease. It is true that there are many cases in which the seat of pain is the same as in the more formidable cases, and yet in which the pathology is very different, and the prognosis by no means grave. For in the latter cases the irritation starts from the gastric nerves, and the reflected pain takes the course of the same nerves as are involved when the irritation has sprung from the heart or the aorta. In hysterical cases it is probable that the irritation begins either in pelvic nerves or in the emotional centre. But these gastric and hysterical cases stand in the same relation to the true angina pectoris as the sympathetic headache to the true nervous headache, the pathology of which begins and ends in the cerebral nerves themselves. But the primary angina is dangerous, while the primary cephalalgia is a slight malady, and the reason is obvious. The nerves of the brain having no other obvious functions than those of transmitting impressions and of regulating capillary circulation and molecular nutrition, may be disturbed in this as in many other organs without serious detriment. But who can say to what extent those ganglionic nerves, which regulate the rhythmical motion of the heart, and the life of which is the life of the heart itself, who can say how far they can

be safely interfered with? It is true, they may be sympathetically affected without injury. The varying rate of the pulsation in a thousand disorders, and the irregularity in others, denote that reflected perturbation does not necessarily imply danger. But when such perturbation begins in the heart itself, whether from degeneration of its substance or from disease of its nutrient arteries, and even when the disease is only in the aorta, it betokens a profound lesion, the influence of which may at any time be fatal. When this change takes place in the life-giving nerves of the part, who can say? Extreme disease may have been ascertained, and yet very little trouble may be occasioned, because that which after all is most vital has not been touched. When we discover after death disorganization to the greatest degree, we are often compelled to admit that amidst all that change and wreck, there is nothing visible that tells why the instrument stopped its action just when it did, rather than months or even years before.

**Statistical Memoranda.**—In order to obtain some numerical data as to the frequency of certain presumed causes of headache, and as hospital registers would not supply information respecting cases which only casually come within their scope, I distributed some circulars of queries, for obtaining replies to which I am much indebted to many of my professional friends. They were queries which were easily answered, and that the answers were for the most part given thoughtfully and carefully, was obvious from their consistency in themselves, and from the general agreement between the different respondents. Though I cannot bring forward any very new results from the answers, yet they afford confirmation to many of the remarks which I have ventured to make upon the disorder under consideration.

We may first direct our notice to those points which indicate a neurotic susceptibility on the part of the subjects of the disorder.

Of 90 cases 76 were females. These numbers establish more strongly than I should have expected, the fact, which is testified by most of the old writers, that females are more frequent sufferers. If we endeavour to ascertain whether this liability of females bears relation to their sexual functions, we do not find much to support this supposition. Of the 76 females, 40 were single; out of the 76 there were 35 who referred to the periodical health as having been in some way connected with their attacks; very few dated from puberty—but a large number from early life. Of the 22 out of 90 who referred to previous illness, none specify illness referable to pregnancy or parturition. In 11 loss of blood is mentioned, but while some speak of it as artificial, none refer to menorrhagia, or to the floodings of abortion or childbed. Now, every practitioner must have noticed that women who have suffered from such losses have been very liable to headache, but it is clear from the replies in general that the specially feminine proclivity to headache is independent of these casualties. But we have said that 35 did refer to the periodical health, and the result of my cross-examination in many of these cases brought me to the conviction that the menstrual function only presented occasions of offence, exciting causes as we often call them, but that the earlier antecedent was a constitutional liability not dependent on this function.

Putting aside the catamenial function, we inquired into the mode of life, and found nothing to lead one to suppose that this was importantly concerned in the production of female liability.

The predisposition more probably originates in the nervous system; and it is needless here to adduce proofs of what is admitted on all hands, that nervous mobility, irritability, hyperæsthesia, or by whatever other name we choose to designate susceptibility of nervous disorder, is oftener found in the female than in the male subject. It is likely to exist in organisms which evidence a capability of so much fineness and delicacy of perception, united with so much proneness to emotional excitement, and in which also we observe the functions of organic life to be so readily wrought upon by passing states of thought, sensation, and emotion.

Of the exciting causes, I find that emotional disturbance has the highest number. Out of 90 cases, 53 declared this to be one of the causes of their attacks; 48 also considered that atmospheric states were to be blamed; and 25 specified thunder.

It would be little better than a platitude to say that it is far more difficult to trace the origin of a predisposition super-

induced on the system, than to indicate causes nearer at hand. Accordingly, in these answers, although the questions afforded sufficient opportunities of stating circumstances in the mode of life, occupation, habits, climatic influence, etc., which might have begotten the tendency, yet very little light is thrown on this subject by the answers. And I incline to the belief, that the cause of this tendency lies too far off to be reached by reference to the experience and consciousness of the individual. It lies in the original mould of the nervous system. This conclusion is supported by the fact that 44 had suffered from very early life, and a large proportion of these used the formula "as long as they could remember." An additional presumption appears from the proof of inheritance of the liability. In 19 cases the mother is mentioned, in 9 the father, and in 12 both parents; in all, 40 give explicit evidence of hereditary predisposition, and a few others mention cases in collateral branches.

The negative evidence as to diet is curious. Out of the 90 cases only 19 blame their diet, and these, if they specify any at all, only mention some article of food which has been at times an apparent and immediate cause of disturbance; of the remainder, 62 deny that diet has anything to do with their attacks; and 9 make no response, or a very indefinite one.

For these negative results as to diet, there are two obvious reasons: first, that people are very slow to observe the gradual or habitual influence of any system of diet into which they have fallen by custom or association; and secondly, that if food does not produce marked disagreement in the first stages of digestion, they are ignorant of what passes in the duodenal and subsequent processes.

As to the influence of climate in augmenting the predisposition, more evidence is given. Thirty-nine either say that climate is a matter of indifference, or they make no answer. But 29 seem very clear that they are least liable to attacks of headache in places where the air is dry and bracing; 6 commend cold atmosphere, 6 condemn it; 8 praise warm atmosphere, 3 dislike it; 6 are in favour of sea-air, and 4 are averse to it. I do not attach any great importance to the paucity of answers as to marine air, because it was not particularized in the questions. Still, if sea-air, *quid* sea-air, had made any great impression, either as a friendly or as a hostile agency, I think it would have come out in the answers.

*Fatigue* is mentioned as an exciting cause by 32, though, from inadvertence, the queries contained no pointed reference to it.

Some of the questions were framed with the view of ascertaining how far numerical statements would bear out the prevalent notion of a connexion between headache and disorders of the digestive organs.

Out of the 90 cases, 33 said that vomiting or nausea occurred in their attacks; 12 reported nausea only; 35 experienced neither; 10 made indefinite answers, or none. Of the 45 cases of vomiting and nausea, 33 declared that the vomiting came on after the accession of pain. Of the rest, 6 spoke of the sickness as simultaneous, and 6 gave no evidence on the subject.

To the question whether the pain had been relieved or removed by sickness, 18 of the 33 said they had been relieved sometimes or partially, and 2 said the pain had given way after prolonged vomiting. Of these one used the expression, "after bringing up pancreatic juice."

These answers would scarcely lead to the inference that the headache depended on the presence of anything in the stomach; for though 18 of those who had vomited spoke of being relieved, this term is very vague, and it is all but impossible to separate the mere effects of the act of vomiting on the circulation and the nervous system, from what might be due to the ejection of food or morbid secretions from the stomach.

Not more satisfactory are the replies to the question as to the action of the bowels. Of the 90 only 12 distinctly affirmed any relation between their headaches and the action of the bowels; 54 denied any connexion; 17 gave ambiguous answers, and 7 were silent.

And in reply to whether they had derived relief from aperients, only 15 gave distinctly affirmative answers; 17 said "sometimes," or used other qualifications; 6 were doubtful; 3 were certain that they were made worse by aperients; 36 declared that they were not relieved; and 13 gave no distinct response. These replies do not tell much either way. When aperients have been taken the pain generally subsides.

spontaneously before the bowels have acted; and therefore even with all the disposition which most patients manifest to attach undue importance to this function, they would not assign the relief to the action if the action occurred subsequently to the relief of pain. And yet we know theoretically that they might do so, since the artificial impulse given to the function of the small intestine may have removed sources of irritation. On the other hand, the affirmative respondents are as likely to have unconsciously set their replies into consonance with their preconceived notions of the value of aperients.

To have asked my catechumens whether their headaches had anything to do with bile or bilious disturbance would have, I well knew, called forth a chorus of "Yes." But as I should have been none the wiser, I thought it better to limit the question to the "accumulation of bile manifested by the skin."

Of the 90, 65 were obliged to say "No;" 14 gave a doubtful or qualified "Yes;" and 11 were mute. When asked if they were liable to indigestion, 39 answered in the affirmative, but with qualifying terms, indicating that they were not quite certain about the matter.

I will not trouble you with further details, but as far as these replies bear upon the relation between Headache and disordered digestion, the evidence is to say the least ambiguous and unsatisfactory. But if any decided inference is to be drawn from it, we must conclude rather against the existence of such a connexion in many of these cases, and we do not advance beyond the fact that when there is the disposition to cephalalgia, the digestive organs may afford occasions of excitement to that disposition.

Two of the questions were intended to elicit facts as to the dependence of the attacks on hypersemia. Of the 90 cases, 38 reported that their headaches were increased by the recumbent position, 27, that they were relieved, 5 were doubtful, and to 17 it was a matter of indifference. Of those who were relieved, some said that the position at first was painful, but afterwards, that it became comfortable; and others appeared to think that the rest was quite as important an item as the recumbence. Change of posture, of course involving motion, almost uniformly aggravates the pain; and we may fairly suspect, that of those who say that the pain is increased by laying the head low, some have been deterred from fairly trying it by the first discomfort of the change.

To the question whether the pain was relieved by stimulants, 35 answered in the affirmative, 30 simply denied, 8 reported it to be absolutely increased, and the remainder were doubtful, or indifferent, or had never tried such remedies. I do not think that much value can be attached to these answers. A headache may be associated with passive congestion, and may be relieved by stimulants. It may be purely nervous, and yet aggravated by them, because in so tender a state of the nerves the slightest increase of vascular disturbance will increase the suffering, whether produced by exciting drinks, or as we have just noticed, by slight changes of posture.

The inquiries as to the operation of these and other agents were made, chiefly to obtain information as to the pathology and etiology of the disorder. But one general question was put as to therapeutics:—"From what kind of remedies have you derived most relief?" The question was too wide; for, while some enumerate the remedies which have done good at the time of pain, and also those which have lessened the frequency of returns, others have confined themselves to the treatment which has relieved the attack. Twenty-six specify benefit from *tonics*, *quinine* being mentioned oftener than any other; 15 mention *sedatives*; 11 insist on profound *quiet*; 4 speak well of *cold applications*, 2 of *warm*; 1 ascribes relief to *leeching*, and 1 (the same respondent) to *blisters*; 3 are so unenterprising as to have tried nothing; 12 have been altogether unsuccessful, and they now rely only on time and patience. The rest give vague answers, not requiring further comment.

As far, then, as the information is positive, we may say that the evidence is in favour of *tonics* and *sedatives*.

It is curious that, in the whole series no mention is made of phlebotomy or cupping; and leeches are noticed only by one person. Had the same set of questions been answered five-and-twenty years ago, I presume that antiphlogistic remedies would have received more notice.

Before closing this statistical attempt, I may mention that of the 90 cases, 43 report that the attack comes on very early

in the day—most of them on *waking*. It would be easy to speculate on the cause of this general fact. Some would blame the position in bed (a); others the long interval after food had been taken; others the state of the nervous centres belonging to sleep; others the diminution in the intensity of terrestrial magnetism in the morning. For my own part, I wait for further illumination on this as on many other topics belonging to the whole subject.

THE END.

## ORIGINAL COMMUNICATIONS.

### THE PHYSIOGNOMY OF INSANITY.

By JOHN CONOLLY, M.D. D.C.L.

Consulting Physician to the Hanwell Asylum.

#### No. 7.—SENILE DEMENTIA.

THE Illustration accompanying the present paper represents the last stage of mental life in a man of great acquirements and well-exercised mind. In such men, if they are also blessed with a tranquil temperament, the approaches of age are gradual, and scarcely painful; or, at least, the gradual failure of bodily strength, the less vigorous digestion, the diminished desire for voluntary muscular exertion, are borne patiently. Quiet pleasures remain; a love of reading; an interest in other men's activity; a sympathy with the vigorous exertions of younger relatives, and with their achievements, if they achieve anything; and also a fondness for the progress of scientific or moral truth. It is not until the individual begins to recognise that his mental powers are also obeying the universal law, and losing their activity or their power, that he begins to feel the sorrow that is incurable, or which will only yield to insensibility. Unwonted fatigue after ordinary mental occupation; indisposition to some recurring task, formerly not felt a task; a disposition to postpone what requires thought; and a perception of some treacheries of memory, are as long as possible regarded as accidents, and sometimes ingeniously accounted for, so as to leave the reflections undisturbed. These interruptions become more frequent, and at length the conviction forces itself upon the sexagenarian mind, that it is entering upon the beginning of the end of a short and unsatisfactory existence. Those who are wise enough to consider this rightly, and are the masters of their own actions, prudently apportion their exertions to their declining powers. Those whom necessity debars from this, go on working until paralysis or death overtakes them. Some part of the nervous structure becomes faulty; and nervous energy is faultily transmitted, and the body or mind, or both, suffer: a limb becomes useless, or the memory fails, either as a treasure of the past, or as the secure depository of superadded things of daily occurrence. It happens, too, that the period of human life when these infirmities gather over a man is one exposed to peculiar sorrows; not only the death of early friends, to which the survivor finds some means of reconciling himself, but the unexpected loss of younger objects of affection, and other blows, which make sudden havoc in the senile brain.

In this Illustration we fancy that we see represented an individual on whom the oblivion of years has crept gently: one who has gone on day after day, for a great part of his life, with occupations demanding talent and accuracy, but of which he was perfectly master. By slow degrees he grew incapable of continuous attention to minutiae, now and then became puzzled, now and then forgetful, and dreamy and drowsy; wondering, meanwhile, what soporific influence was overshadowing him, and comparing himself to a man in a kind of mesmerised sleep. The figure represents a venerable ruin. In the finely-developed head we seem to read an equally well-balanced mind; without extravagance, without extremes. The eye is large and meditative, the nose well pronounced, the lower jaw indicative of steady-

(a) I was curious to see if there was any coincidence between the fact of accession of pain in the early morning, and increase of pain by recumbency. Of the 38 cases who reported such increase, I find that only 16 report their attacks to have been of early occurrence in the day. If this is of any value at all, it would be adverse to the notion that position has anything to do with early accession.

ness and strength. In the upper lip there is, perhaps, a want of compression, belonging to the approaching dementia. The whole figure, and also the drooping eyelid, bespeak repose. It is happy for old men when this repose is seldom disturbed. Few of them are so privileged as not to feel from time to time a sort of pang of mental dissolution, or something like sensible accessions of old age, and an unavailing sorrow that all they valued perishes in this world, even as the less regarded elements of their bodies. And to mortal man such mortal experiences are real afflictions. To find the sight less acute, and the ear blunted and treacherous, and the limbs heavy, and the voice tremulous; and, worse than all, the glorious faculties of the mind gathering some strange dimness, the reflection faulty, and the imagination fickle and flighty, is to be sensible of the approaches of death; and actually to feel how gradually and yet how surely "this sensible warm motion" is becoming "a kneaded clod."

Some of the great painters have recognised in these cases of old men the beauty that still hovers over their decay. In these reposing features they saw perhaps more clearly, as well as in the form of the head and face, the distinctive beauties of the inherited and acquired individuality of expression. The bony formation, inherited, or at least congenital, gives a fixed and determined shape to each face, whilst the muscular portions of the face and forehead have taken a character in most instances from the events of the individual's life, and the emotions they have excited in the brain, under the entire command of which nearly all the facial muscles seem formed exclusively to act. But these muscular modifications are also occasionally inherited, and the child's features bear a strange impress of the forgotten griefs of once unhappy ancestors. On the other hand, persons of ardent disposition, who have worn all through their active years the physiognomy of an excitable mind, sometimes lose by degrees all this muscular agitation, and as they descend into the calm twilight of age, revert in appearance to that of parents or uncles or aunts still remembered by friends of the family. After death the face often exhibits these resemblances; and, above all, the placidity which human events can disturb no more. When there are exceptions to this, and the countenance bears in the latest years of life the stamp of mean or angry sentiments, which sometimes, indeed, shock our observation even in the coffin, the effect seems to be a result of the habitual impress of such feelings on the muscular part of the physiognomy during the greater part of life, with few or no benigner alternations.

The great size of the cranium in man compared with its limitation in animals, has attracted the attention of all anatomists and observers. The perpendicular forehead of the lion, and the broad front of the elephant, although superior to the low forehead of the tiger and to that of almost all the lower animals, yet contain a brain smaller, less complicated, and manifesting far fewer endowments than that of man. In the gradual growth of an infant, the prolonged head of the time of birth, and the prolonged occiput, are gradually gathered into a more compact or rounded shape; before the time when the tender and separated bones of the infant's skull become firmly and permanently conjoined and thickened, so as to assume a character scarcely admitting, if admitting at all, of subsequent modification. The process is not completed with perfect equality as to time or shape in different individuals. The inherited constitution, and its modification by various nourishment, or by incidental diseases in infancy, childhood, and youth, affect the development of the forehead, vertex, occiput, and lateral portions of the skull, and produce the distinctive forms observed in different persons, and which become even characteristic of particular families. In many insane persons such modifying causes seem to have determined the narrow or retreating forehead, the lofty vertex, and the bulging occiput; while in others the shape of the skull presents little or no peculiarity; and, generally speaking, the peculiarly shaped head mentioned indicates an incurable form of malady. Supposing the structure and integrity of the cerebral substance to be the same in two insane persons distinguished by such formation of head, more hope would exist in the one in which the forehead was amply or reasonably, or normally developed, and the vertex and occiput were not in excess. But a diseased brain may exist in a bony skull-case of any shape.

The general deficiency in the development of the heads of idiots, and its equally morbid redundancy in some of them,

are circumstances which may now be easily verified in the asylums for these unfortunate beings.

It is probable that causes similar to those affecting the comparative growth and gradual development of different regions of the skull, produce the like effects in the bones of the face; influencing the depth of the orbits, the size of the nose, the breadth of the malar bones, the squareness of the jaw, and the character of the chin. These parts at length reach their ultimate shape; and are often undeniably associated with definite mental character; as well as with muscular and other physical characteristics, allying the fixed and the moveable parts of the face with a resulting consent and sympathy, and by this conjunction producing physiognomic expression.

The same laws are exemplified in the trunk and the limbs; and each special development is usually associated with a special mental character. National characteristics of feature are also probably produced by various combinations of causes as family faces are; but causes more diversified and numerous, and acting for a longer time and more exclusively on successive descendants or generations.

Such elaborate anatomical arrangements exist for facial expression as quite to exonerate the physiognomist from the charge of pursuing a vain science. The medical student well knows how minute and delicate a work is the dissection of the muscles of the face. But the observations of Mr. Charles Bell, in his able work on the Anatomy of Expression, still strike the reader, even the anatomical reader, as conveying some things which he never thought of before; and singularly illustrative of the importance of that external facial expression in God's most intellectual creature; in whom a provision for it is made so far exceeding anything of the same kind in the lower animals, where it is yet singularly provided for, as to afford one among innumerable instances of the wonderful adaptations to ends by the Creator of all life, and the Giver of all intelligence.

Of the numerous muscles of the face, all except the two which move the lower jaw may be said, says Bell, to be muscles of expression. They arise from some point of bone, and are inserted in the moveable integuments of the face. Many of them are peculiar to man, and endow him with a much wider range of facial expression than is possessed by any of the lower animals; and commensurate with his superior mental faculties. Some of them contribute also to the movements indispensable to the modulations of his more expressive and varied voice. The large muscle which covers the head from the occiput to the eyebrows, the transverse muscle between the eyebrows, and the circular muscle covering the eyelids, and surrounding the space under the eyes, contribute to the elevation, and depression, and corrugation of the forehead; movements largely connected with varied expression; and the same muscles close or open the eyes themselves, according as joy, or sorrow, or anger, or other emotion affects the mind. There are separate muscles for raising the soft side portions of the nose, and also the outer angles of the upper lip, and also for depressing them; others for raising the whole upper lip, and for depressing the whole lower lip; and these various actions produce expressions known as indicating gaiety, or melancholy, or contempt, with various modifications.

The accidents of life, and the reaction upon them of the individual mind, exercised on these organs of expression for a length of time, may reasonably be expected to leave, in general, some traces there. But the relations of physiognomy sometimes extend far into antecedent years, and lie among the virtues and faults of a well or ill distinguished ancestry, remembered or unrecorded. It is not usually the history of the individual alone that is carved on the sexagenarian face. The subject of physiognomy is not merely curious; although it has never yet been thoroughly considered, being erroneously judged to be chiefly founded on fancy. The whole of an individual's life is often written in the countenance, but no legible at a glance.

The repose of the features in Senile Dementia is usually complete. Ambition is dead, angry emotions have passed away; mean and turbulent thoughts, if any there were, have become extinguished, the life of the passions is over. Man has become a peaceful animal; rarely, when the state is once established, disturbed by any shadows of the past years. This perfect calm is, however, sometimes preceded by great agitation, and fancies of some work to be done, or some

engagements to be fulfilled; leading to attempts to wander away from home, and to resist the most affectionate control of grieved relatives. But peace succeeds, greater than the peace of childhood; and then, sometimes, the spectacle of extreme age loses its painful character, and becomes eminently picturesque. Few of my medical readers, however busily engaged in crowded cities, have not treasured up in some corner of their minds, among the recollections of childish days, some picture of a venerable aged man or woman seated at a cottage door, seeming to view with calm face and untroubled heart the sweet meadow and the declining sun; or looking with satisfaction on the juvenile activity of their active and joyous grandchildren, although with a vague consciousness and a dreamy expression. Sorrow could not touch these remembered old people further; but all of sensation that was left seemed to be pleasurable.

It is, however, a strange thing to look on a face once most familiar to us, and now, when nearly ninety years have gathered over it, still to see the same features, and even the same smile, and yet to be forced to the conviction that you are not recognised. The placid features, the benevolent regard, the long grey hair, are but a venerable picture. The activity of former years is a dream. No word, no sign, not the most pointed allusion to things past, and once most familiar, rouses any responsive movement in the senile brain. Life still remains; respiration, and digestion, and blood-circulation, and alternate waking and sleep; but memory, and emotion, and speculation, and foresight, and with them, happily, anxiety and sorrow, and pain and grief, have passed away.

Even this is better than the strange mixture of the mournful and the ludicrous in cases, in which, amidst the wreck of all nobler things, the memory of life's poor vanities alone survives: and the old lady who can scarcely rise from her chair, insists on being dressed and rouged, and seated at the card-table, where her pleased, but utterly foolish expression of face, reflects the thoughts of gains or losses, which once constituted the only serious events of her daily life. Even a man's mind may show these infirmities, where an ignoble and frivolous life has left him insensible that he is mortal. In one remarkable case of this kind, in a well-known fashionable man of his day, considerable mental acuteness was, all the life long, so assiduously devoted to things below the dignity of a man, that when age came it brought with it, on each return of evening, a return of the fancy of a room full of the grand and gay, of wits long silenced and beauties long hidden in the grave; and the poor worn face of age was lighted up with an inane gaiety that shocked the beholder. Thinking of these things, one feels the beauty as well as the simplicity of Lavater's farewell words to a youth taking leave of him:—"Young man, bring me back the same face;"—a face undeformed by vanity, or falsehood, or guilty thoughts.

#### NOTES OF

### PRACTICE AMONG THE OUT-PATIENTS OF ST. BARTHOLOMEW'S HOSPITAL.

By JAMES PAGET, F.R.S.

Assistant-Surgeon to the Hospital.

#### No. V.—ON THE DIAGNOSIS AND TREATMENT OF ULCERS OF THE TONGUE.

In this, and in the following paper, I propose to give the results of observations, made chiefly in the out-patients' room, on some of the diseases of the tongue, and especially in relation to the diagnosis of those of its mucous membrane.

And, first, of ulcers of the tongue:—they may be thus classified:—

1. Simple. *a.* From superficial inflammation. *b.* From constant irritation, as by a rough tooth.
2. Aphthous.
3. Mercurial.
4. Syphilitic: *a.* superficial; *b.* deep; *c.* inherited.
5. Strumous.
6. Cancerous; *a.* superficial, or papillary; *b.* deep or massive.
7. Tuberculous.

1 (*a.*) Simple superficial ulcers of the mucous membrane commonly occur, with a general florid bright congestion of the surface of the tongue, in dyspeptic people, and those who habitually eat and drink too much. They are usually small, superficial ulcers or abrasions, very sore and sensitive, with no definite shape or plan. They are not likely to be confounded with any other ulcers, unless with the superficial syphilitic. From these they differ in their acute course, in their being about the tip, rather than the sides of the tongue, and in the active congestion of the mucous membrane which is generally associated with them, and only seldom, or as by accident, with the syphilitic.

The obvious remedy of ulcers of this kind, when they are due to excess, is reformation of diet and active purging. If they survive these, they should be touched with nitrate of silver. When they are only occasional consequences of habitual dyspepsia, the same local means will be useful, but, of course, they cannot be finally cured except by the remedy of the dyspepsia.

When these ulcers occur at or near the frænum of the tongue, they are sometimes so small that they are apt to be overlooked; yet they are extremely painful, and may endure long, or frequently recur.

1 (*b.*) Ulcers of the tongue, due to the irritation of rough or sharp-edged teeth, vary much in appearance, according to the general condition of the patient, their date, and many other conditions. They may be like rough excoriations, with shreddy foul bases and borders, ill-smelling, surrounded with swelling, and a sodden, but not hardened, state of the tongue. Or, with similar general characters, they may extend deep into the tongue; the surface of the tongue, and of the adjacent part of the gums, being in both of these cases covered with a thick creamy or pasty layer. Or, again, while the rest of the tongue may be nearly healthy, the ulcer of more chronic progress may be well-defined, regular, clean at its base, with upraised, rounded, and hard "callous" borders.

Due regard to the teeth will usually determine both the diagnosis and the remedy of these ulcers. But, it must be noted, that so long as the general health and digestion are good, the tongue may tolerate without damage the irritation of rough teeth. Patients, therefore, knowing that their teeth are not unusually bad, will ascribe the ulcer of the tongue to any cause but them; and, even after the removal or smoothing of the teeth, the ulcers may not heal till the general health is improved. And, again, cancerous disease may be determined to a particular portion of the tongue by the constant irritation of a tooth; and extraction will only for a time diminish the activity of the disease.

2. Aphthous ulceration of the tongue may scarcely need description, for its frequency in children may make it easily known when, more rarely, it is seen in adults. With general heat, increased secretion of saliva, and general redness of the mucous membrane of the tongue, (the lips and gums also commonly participating,) aphthous ulcers appear as small, flat, circular, or oval ulcers, following vesicles. They are sometimes single, and may then be nearly half an inch in diameter; but more commonly they are clustered about the fore part of the tongue, or appear in successive crops. Their bases are smooth, greyish or yellowish, with very thin adherent slough; and their borders are well defined, not only by the cleanness with which the superficial layer of mucous membrane is removed, but by the bright crimson areola which surrounds them without elevation or hardness.

With these characters, there is usually active gastric or intestinal irritation. The healing of the ulcers will follow that of the irritation, but will be helped by the application of nitrate of silver in substance or strong solution.

Aphthous ulcers of the tongue may be confounded with the simple and the syphilitic, superficial ulcers. The safest distinctions will be found in their acuteness, the sloughs on their bases, the bright areola, and the attendant active irritation of the stomach or intestines.

3. Mercurial ulcers of the tongue, such as occur in or after ptyalism, may generally be known at once, by the attendant affection of the gums, with pasty deposits at the teeth, by the peculiar fætor from the abundant decomposing saliva, by the general enlargement and sodden state of the tongue. In a former paper I have spoken of their treatment.

4. Strumous ulcers of the tongue (as I believe they may fairly be called) are rare. They occur most frequently in persons under 20, and I have not seen an instance after 30.

Their usual chronic course is, that they commence in one or more lumps in the substance of the tongue, lumps that are deep-set, firm, compressible, elastic, ill-defined, and little, if at all, painful. With slow progress, each lump seems to proceed to central suppuration, and thence to ulceration. Hence is derived either a small irregular opening into the central cavity, or, more commonly, a larger irregular ulcer, with a flat tough base, unequally excavated, and with thick unequal overhanging margins. The ulcers may slowly extend, but they generally remain long stationary, just not healing; and the parts about them become thick, tough, and large, as if with chronic inflammation in all the adjacent textures of the tongue. Even after the ulcers are healed, I think the enlargement may increase, and produce a peculiar form of hypertrophy, with toughness, pallor, and an uneven seamed and scarred surface.

The likeness is evident between this disease, in all its essential features, and that which we recognise, in other parts, as strumous abscess and strumous ulceration. This is not merely chronic abscess, for abscesses of very slow progress do occur in the tongue, and when they are emptied they heal quickly, and the recovery is complete. But, on the other hand, these strumous diseases of the tongue differ from both the syphilitic and the cancerous (with which they are most apt to be confounded), by the ulceration being usually preceded by distinct suppuration. Other diagnostic characters are, that the induration that accompanies or precedes the strumous ulcers is never intense or well-defined; it is, rather, a toughness with diffuse enlargement, not nodular or warty, not painful, not usually accompanied with lymphatic disease. These characters, however, may be insufficient to distinguish strumous ulcers from those of inherited syphilis, to which I shall presently refer. The diagnosis may be assisted by the existence of other marked strumous affections, or, if not by these, by the test of treatment. Iodide of potassium will quickly heal the syphilitic ulcers; but will very slowly, if at all, do good to the strumous. The only remedies for these are the same as for strumous disease, of similar type, in any other part; especially, I think, the cod-liver oil.

5. Syphilitic ulcers of the tongue occur in at least two very different forms, the superficial and the deep. The former are related, in their nearest analogy, to the cases of syphilitic psoriasis of the palms and soles; the latter to the deep ulcers which follow subcutaneous indurations (or gummata), such as one sees especially about the upper part of the leg, or more rarely in the lip or cheek. The superficial, occurring usually with similar disease of the lips, are among the later and most inveterate secondary symptoms; the deep are tertiary. In what measure any of them may be due to mercury or iodine, as well as to syphilis, I cannot say; but I have seen no reason to believe that either mercury or iodine alone will produce any of them.

(a.) Of the superficial ulcers, the most common are such as appear at the sides of the tongue. Some of these, indeed, may not deserve the name of ulcers; for they have thin coverings of epithelium, and do not bleed when even roughly touched. They may be like little oblique or starred fissures in the edge or tip of the tongue; or may appear as pale, bald, raw patches on the mucous membrane; or as such patches, with deeper ulceration at their centres; or, again, there may be single, flat-based, defined, and thin-bordered ulcers through nearly the whole thickness of the mucous membrane; and with any of these forms of the disease there may be round the ulcers little groups or clusters of florid prominent papillæ.

All the superficial syphilitic ulcers of the tongue are very sensitive and sore; but there is little increase of vascularity in or near them, except in cases of accidental complication, through gluttony, intemperance, or other exciting causes. In their long duration, nearly the whole surface of the tongue may become opaque-whitish, or pale purple, smooth, as if without papillæ, and fissured, and the whole organ may become large and thick.

Except the worst cases of cachectic syphilitic ulcers, I believe no affections of the kind are so nearly incurable among out-patients as these forms of disease of the tongue. Among those who cannot use the moist mercurial fumigation (and such are most out-patients), I believe that the best general plan is to give a grain of calomel and half a grain of opium every night, for not less than two months. This plan will certainly cure some, and do harm to none, and improve

many whom it does not cure. For local applications, none seem to give more comfort than the occasional touching of the sores with the solid nitrate of silver, and the frequent washing of the mouth with a lotion containing one or two drachms of the diluted nitric acid in a pint of water.

I have already said that simple superficial ulcers of the tongue may generally be distinguished from the syphilitic, chiefly by the concomitant florid inflammation of the mucous membrane. Similar inflammation, accidentally associated with the syphilitic ulcers, may make the diagnosis doubtful; but the doubt is not practically important; for a rule holds here, as in many other cases; namely, that it is not advisable to give specific medicines while active inflammation accompanies specific disease. The inflammation must be treated first, then the specific disease; and in the case of superficial ulcers of the tongue, if they do not quickly heal when the inflammation passes by, the diagnosis of syphilis is made more clear.

(b.) In the case of the deep syphilitic ulcers, we can commonly see or hear of one or more preceding lumps of firm, inelastic indurations, well-defined, enlarging the tongue, and covered with tense, adherent, smooth, and glossy mucous membrane. The usual seat of the induration is in the upper part of the tongue, often extending far back, but rarely affecting its borders or inferior surface, and still more rarely reaching the floor of the mouth. The induration may, for two or three weeks, only enlarge; under treatment it may clear away; but more commonly it softens, and then either sloughs or ulcerates at its centre. The ulcer which succeeds is deep, excavated, sometimes angular, or cleft-like, with no regular form, bounded by the remains of the induration. Its borders may, at first, be ragged and sloughy; but they soon become smoother, and then appear as edges of thickened and hard mucous membrane, overhanging the cavity of the ulcer, and sometimes nearly meeting over it, so as to need to be parted that the cavity may be seen. In this state the ulcer has no great tendency to spread; its disposition is rather to become indolent, half-healing, with increasing toughness of its boundaries, but without material enlargement of the tongue.

(c.) Ulcers so like these that I can name no difference, may be found in the tongues of young persons that have had no primary syphilis. I have already said that I believe them due to inherited syphilis. These cases, therefore, differing from the last-described only in their mode of origin, may neither need nor admit diagnosis from them; and the treatment of both is the same.

The other forms of ulcers of the tongue, with which these may be confounded, are the strumous, cancerous, and tuberculous. The diagnosis of the first has been already pointed out; that of the last will follow. From cancerous ulcers, the deep syphilitic may generally be known by their induration being less intense, not nodular; the mucous membrane over or near them smooth or glossy, not warty; their borders overhanging their bases, not everted or nodular; by the little pain that attends them if they are not inflamed; by their being at, or tending towards, the dorsum of the tongue, rather than its sides or the floor of the mouth; by the absence usually of sympathetic disease; by their progress to ulceration occupying usually less than a month. Of course, a history of syphilis may help the diagnosis; but, the less it is relied on the better, unless other syphilitic affections be actually present. The age of the patient may also have some weight; the younger the less the probability of cancer.

If all these indications for the diagnosis fail, it may almost securely rest on the effect of treatment. Iodide of potassium will quickly cure, for a time, the syphilitic ulcer, but will have only a slight and transient influence on the cancerous one.

It is possible that a difficulty might happen in the diagnosis of syphilitic or other indurations, and fibrous or fibro-cellular tumours in the tongue. The distinction may be found in the tumours being of slower increase, moveable, and covered with healthy mucous membrane that slides over them.

6. Of cancerous diseases of the tongue one may observe two chief forms, both epithelial; namely, the superficial or papillary, and the deep-seated or massive; and, although cases may occur that confuse them, they are in general sufficiently distinct.

The superficial cancers before ulceration resemble most nearly the syphilitic condylomata and other diseases of the papillæ and mucous membrane, which will be mentioned in

the next paper. The best distinctions will be found, generally, in that the cancers are more warty, or manifestly papillary or tuberculated, and more suddenly upraised and defined at their borders, than mere indurations of the mucous membrane are; and are more deeply seated in the very substance of the tongue, and thicker, (being seldom less than a quarter of an inch thick,) and have more defined and harder bases than the condylomata have. Generally, too, the cancers, even before ulceration, are attended with more afflux of blood to the adjacent parts of the tongue, and with a larger flow of saliva, and more pain both in themselves and about the ear, and jaw, and side of the head, than any of the diseases that at all resemble them. In their ulcerated state, the superficial cancers have additional diagnostic signs in their central ulcerated surfaces, or fissures, or excavations, surrounded by well-defined induration, the extent and depth of which are not diminished by the extension of the ulceration. The base of the ulcer is generally hard and uneven, coarsely granular, papillary or nodulated; and the borders are, generally, lobed, like pieces of conglomerate gland, sinuous, upraised, and, if the disease is active, everted over the surrounding surface. If the case can be watched, all these characters become more marked, and others yet more distinctive are added; such as the fixity of the tongue by the adhesion of the base of the ulcers to the adjacent parts, the enlargement and hardness of the submaxillary lymph-glands, a condition very rarely found with any other ulcer of the tongue, unless it be acutely inflamed. Late in the disease, too, there will be a cachectic aspect; but I have never seen this till the other signs of cancer were so well marked that there was no need of it for diagnosis.

The massive, deep-seated cancers of the tongue are very rare. Before ulceration, and while the mucous membrane is not involved, they may resemble the syphilitic lumps, or the fibro-cellular tumours, or, with far less likeness, the deposits that precede the strumous ulcers; but, of all these, I have already named the diagnostic signs.

I have little to say of the treatment of cancers of the tongue. As a general rule, it is right to remove them whenever this can be done safely and freely, and the *écraseur* is an admirable instrument for the operation.

7. Tuberculous ulcers of the tongue are rarer than any of those now described. The best case I have yet seen was in a policeman, 37 years old. Nearly the whole of the right lateral surface of the tongue was ulcerated. The outline of the ulcer nearly followed the borders of the tongue, but was in parts sinuous, or sharply eaten out. Its border was abrupt, neither elevated, nor everted, nor undermined, surrounded with a florid areola; at its base there was a slight elastic and pliant induration. The base of the ulcer was on the level of the superficial muscular fibres; appearing, in some parts, banded, as if the muscular tissue were exposed, in others granulated; only at its posterior part the base was more deeply excavated. The disease was painful, attended with profuse flow of saliva, and very difficult use of the tongue.

In six months, what seemed at first a little pimple had led to this condition. The characters of the ulcer were such as I had seen in no other disease of the tongue; they were very like those of tuberculous ulcers of the intestines; but it might have been impossible to distinguish the affection as tuberculous, if it had not been associated with pulmonary tuberculosis. With this the patient died; and the ulcerated part of the tongue, examined after death, showed no mark of cancerous disease, but exact resemblance to distinct tuberculous ulceration of the vocal cords.

#### THE LONDON

### PRACTICE OF MEDICINE AND SURGERY.

#### THE HOSPITAL PHARMACOPEIA.

In our last notice we passed in brief review some of the principal formulæ in the Pharmacopœia of the Royal Ophthalmic Hospital; we now propose to glance at those of the Hospital for Diseases of the Skin. The first observation which strikes us is that the praise for simplicity of prescription awarded in the former instance must be withheld here. Although we are bound from long observation to say of the practice of Messrs.

Startin and McWhinnie, as pursued at the Cutaneous Hospital, that it is exceedingly successful, yet it is certainly open to some criticism on account of its great complexity. There is scarcely a formula in their Pharmacopœia which does not include three active ingredients, while it is an exception to the rule, if in practice the simultaneous employment of three of these (a mixture, lotion, and ointment), be not ordered to each patient. When we add to this statement that many of the compound formulæ bear names which do not denote their most active ingredients, the reason why students attending this Hospital often complain of the difficulty of discovering the principles of the treatment pursued, will be easily understood. Under such circumstances we should but little serve the objects of our readers, by simply transcribing the formulæ employed, and shall therefore preface our quotations from its Pharmacopœia by a few general observations on the principles of treatment kept in view, and on which we believe the very successful practice of this Institution to depend. In attempting this task we must state that of course the Medical officers are not to be held responsible for our remarks. The latter are, however, the result of several years of punctual attendance on their practice.

First among the elements of success we must note the very fault to which we have adverted,

*Complexity of Prescriptions.*—Whatever as scientific therapeutists we may object to the plan of administering many active remedies at the same time, there can be no doubt but that in the very limited state of our knowledge, it often secures the end in view more quickly than a more simple and restricted one. There are many forms of skin disease, for instance, in which our best dermatologists are far from agreed, as to whether small doses of arsenic, of mercury, or of iodine, will best serve the patient. He who in such uses Donovan's solution, will probably cure his cases more surely than his more accurate and conscientious brother, who labours in each instance to make an exact diagnosis, and restricts himself to a single appropriate drug. A thousand illustrations of this might be given. If the Surgeon, again, in the treatment of external affections, such as those of the skin, not only allows himself to use compound formulæ in attacking the humoral element in the disease, but also resorts freely to the same kind of measures for local use, he certainly multiplies his chances of success. If the mixture do no good the lotion may, and if the latter fail, the ointment applied nightly, or the bishebdomal medicated bath, may perhaps attain the end. We hope we are not furnishing arguments to the idle. We simply state the fact. But there is another and much more legitimate defence to be alleged for complexity of prescription, viz. that the ingredients often act as adjuvants, and mutually increase the powers of each other. In this respect many of the formulæ of this Hospital are most excellent, and have been constructed with great care and skill. We shall have to mention instances very shortly.

The next matter asking for note is,—

The very free employment of strong mineral remedies. The drug bill at this Hospital must be, as compared with the extent of its practice, exceedingly light. Almost no vegetable preparations are ever prescribed, nor are any tinctures used excepting very rarely. Arsenic, iodine, iron, mercury, sulphur, creosote, and colchicum in various combinations do almost the whole duty. In stating that the employment of mineral remedies is "very free," we must be understood to mean general, not profuse. The doses given are almost always very cautiously minute, and very rarely indeed have we observed the occurrence either of salivation, or of iodism, or of arsenical eczema.

To the accuracy of diagnosis, and of prompt recognition of the attendant diathesis, which constant familiarity with a specialty gives, much of the success in treatment to which we have adverted, must of course be attributed. Of this, however, it would be superfluous were we to add more, since it is the very keystone of practice in all departments of our art.

To pass next to the principles of treatment of special classes of disease, and the use of particular remedies.

*Parasiticides.*—The following is the formula for the "Compound Sulphur Ointment," which is in general use against scabies, favus, and true ringworm; diseases which depend upon parasites, which it is necessary to kill:— $\beta$ . Of sublimed sulphur half-a-pound, of the ammonio chloride of mercury

half-an-ounce, and of the sulphuret of mercury half-an-ounce; to these well rubbed together add four ounces of olive-oil, sixteen ounces of fresh lard, and twenty minims of creosote. It will be seen that we have here in combination three different drugs, each possessing great efficiency in the destruction of insect and fungus life. The object in view, that of obtaining a vigorous compound, which at the same time shall not be irritating to the skin, is, we believe, exceedingly well attained. Mr. Startin, however, does not in any of these diseases rely only on the local measures. Patients suffering from scabies always take an acidulated saline aperient while using the ointment, and to those suffering from either favus or true ringworm, arsenic or iodide or potassium are usually ordered. In the treatment of ringworm the application of blisters to the patches is also always resorted to, with the object of removing at once the cuticle and its infesting cryptogams. Favus is at this Hospital acknowledged to be an incurable disease. The scalp may, however, be kept clean by the constant use of the ointment mentioned above, but if it be laid aside even after years of treatment, the disease will to a certainty return (a). In regard to the diseases attended by parasitic growths, Mr. Startin holds with those dermatologists who consider that the constitution of the patient must be peculiar in some respects to admit of their attack. That the fungi, in fact, come as mites to cheese, not to all cheese, but to those only which are well kept, and beginning to decay. There is, we cannot help thinking, very weighty evidence in support of the view which holds that these diseases spread by mere accidental contagion, and the fungus once planted will attack the hairs of any child, quite irrespective of the state of health. Should this be admitted, the use of internal remedies, as a general rule, would be rendered superfluous; and so, indeed, it is, as far as we can ascertain from our own experience. During the last four years in the out-patients' room of the Metropolitan Free Hospital, the writer has never prescribed any specific constitutional measures in favus, true ringworm, scabies, or contagious porrigo, relying wholly upon external applications; and he believes with equally good results as those obtained in the practice of the Cutaneous Institution. Not unfrequently in cases of scabies and porrigo, attended with excess of local irritation, and consequent febrile disturbance (especially in young children), salines and aperients have been ordered, but no cases have occurred in which either arsenic or iodine have been thought necessary.

**Treatment of the Syphilides.**—The treatment of the cutaneous forms of syphilis, which form a large part of the practice of this Hospital, is almost invariably conducted by means of both topical and general remedies. Mercury, and the iodides, of course constitute the bases of the formulæ for these affections. For the earliest forms of eruption, the scaly and papular, for instance, calomel and opium in pill are often ordered, but more frequently the bichloride in solution. The following is the prescription for the *Mistura Hydrargyri Bichloridi* of the *Pharmacopœia* (see page 26):—℞. Of the bichloride of mercury two drachms, of strong hydrochloric acid one drachm, of spirits of camphor two drachms, of burnt sugar half a drachm, of water a gallon. The dose is from a drachm to two drachms, each drachm containing a twelfth of a grain of the bichloride. An extemporaneous biniodide of mercury is also much used, the formula for the mixture being as follows:—℞. Of the bichloride of mercury two drachms, of the iodide of potassium six ounces, of the tincture of cardamoms two ounces, and of water a gallon. Of this, the dose, a drachm, contains a tenth of a grain of the bichloride, and two grains of the iodide. Simultaneously with the use of either of these mixtures, Mr. Startin almost always orders the "Red Ointment" to be rubbed into the patches of eruption, or applied to any ulcers which may exist. The formula for this "Unguentum Rubrum," the prime favourite of the Institution, is,—of the bisulphuret of mercury half an ounce, of the nitric oxide of mercury half an ounce, of creosote twenty minims, and of fresh lard sixteen ounces.

(To be continued.)

## THE VICTORIA PARK HOSPITAL FOR DISEASES OF THE CHEST.

### BRONZING OF THE SKIN IN A BOY—DEATH—TOTAL DISORGANIZATION OF BOTH SUPRA-RENAL CAPSULES BY OLD DISEASE.

(Under the care of Dr. BENNETT.)

A boy, aged 11, tall, thin, and emaciated, was taken by his father to Dr. Risdon Bennett's out-patients' room at the Victoria Park Hospital, on Thursday, April 15. He was stated to have been losing flesh for some time, and getting weak, but he had had no acute symptoms, nor any indications of pulmonary mischief. He had walked to the Hospital, a distance of more than two miles, and after having been prescribed for he walked home again, without making any complaint of unusual fatigue. Dr. Bennett, and Mr. Couzens, the House-Surgeon, both recognised at once, from the lad's complexion, the nature of his disease. His face presented a most marked condition of bronzing, the colour being diffused over the whole surface, but darker in some parts than others. In the centre of the forehead was a patch, of very dark tint indeed, about the size of a halfpenny, and the edges of which gradually shaded in the surrounding less deeply-tinged integument. The whole surface of the body and extremities was discoloured, but not so dark as the face, excepting on the backs of the hands, and on the sides of the knees. On the sides of the knees especially the skin was very dark. There were a few faintly-marked, but indelible streaks on the mucous membrane of the lips, as if caused by light touches with Indian ink. The conjunctivæ were pale, and, on careful examination, no indications of disease within the thorax could be detected. As to the duration of the bronzing, the lad's father stated it had become very much more marked within the last few weeks, but for some time his neighbours had been suggesting that the boy must have the jaundice, and he thought some of these remarks had been made nearly as much as six months ago. He had not considered the lad ill until quite lately, and even up to the present time he had been accustomed to play about almost as usual with other children.

Whether from having been over-done by his long walk, or from other cause, is not clear, but on the day following his attendance at the Hospital the boy was taken seriously ill. He had some slight diarrhoea, with sickness, and afterwards a series of convulsive seizures. After being confined to bed for about a week, he died on the 27th instant. During the last week of life he had been attended at his home by Mr. Edmund Bletchley, of the City-road, who at once recognised the true nature of the case, and to whose kindness the writer is indebted for an opportunity of seeing the corpse, and for an account of the result of the post-mortem.

At the autopsy the brown colour of the skin was still exceedingly well marked. There was but little fat in the sub-cutaneous tissue, or in any other parts. A careful examination of the thoracic and abdominal viscera was made, but, excepting in the mesenteric glands and in the supra-renal capsules, no morbid conditions were discovered. Many of the mesenteric glands were enlarged to the size of marbles, and contained cheesy matter, encapsuled in very dense or even osseous parietes. These deposits resembled in every respect tubercle which had softened, and was now undergoing absorption. In none of the glands was tubercle in a recent stage of progress found. Both supra-renal bodies were totally disorganized, containing chalk, cheesy matter, and firm fibrous structure, binding together these elements. No trace of their normal tissues was discoverable, nor was there any softening, or evidence of recent inflammation. The disease was evidently in process of spontaneous cure, and had existed for a very long time (a).

In commenting upon this instructive illustration of the correctness of Dr. Addison's views, we may suitably direct attention to the fact that the change in colour was so great, and so characteristic, that the nature of the case was recognised at a glance by three different Medical men, who saw the patient on separate occasions during life. Although the lad had not become so feeble as is usual, yet the constitutional

(a) The vaunted remedies for favus so often written about; all of them owe their reputation either to mistaken diagnosis or to hasty observation. True favus is a very rare disease, even at the Hospital for Skin Diseases. Contagious porrigo, an affection easily curable by local applications, is the eruption usually mistaken for it. The microscope would always correct this error, and ought never to be neglected.

(a) The capsules, together with a coloured portrait of the patient, were exhibited by Mr. Hutchinson at the last meeting of the Pathological Society.

\*symptoms had been in kind those commonly observed. The irritability of mucous membranes, with convulsive attacks, which preceded death, were exactly the symptoms noticed in so many previously recorded cases. In connexion with these circumstances let us advert to the fact that except by the disorganization of the supra-renal capsules, the cause of death was wholly unexplained. The condition of the affected mesenteric glands was that of long past disease; and with these exceptions all the viscera were healthy. In all probability the supra-renal capsules had been disorganized by the deposit of tubercle at some period long prior to death. The chalky concretions within the dense fibrous structure, which was all that remained of them, showed indisputably that the work of absorption, and, as far as was possible, of reparation, had been long in process. There was no trace of recent inflammation about them. Now let us note some interesting considerations as to the relation of the bronzing to the disorganization of these bodies. We have often before directed attention to the circumstance that in cases of recent disease of the capsules, however completely it may have effected their disorganization, no change in colour of the skin is to be expected. In such, on the contrary, the peculiar and intense anæmia resulting, usually causes the observer to describe the skin as remarkably pale. In the above case no very reliable account could be obtained as to how long the dark tint had been noticed. It was, however, certain that it had not been present very long. To one inquirer the father said that his boy had only been brown for a few weeks; to another he admitted that the neighbours had spoken of his having the jaundice several months ago. Now supposing that the boy had died six months before he did, it is almost certain that his skin would then have shown nothing characteristic, while the capsules would yet have been found wholly destroyed. It is of such cases that the seeming exceptions to Dr. Addison's law are composed. We are not aware that any single case has yet been recorded, in which both capsules were in a condition that rendered it probable that they had been disorganized for a year or more, and yet bronzing was not present. With regard to apparent exceptions of the converse kind, those namely, in which, while the skin was dark, the capsules were found healthy, we know of no single one which will bear a moment's examination, if the following be borne in mind, as the characters of the true supra-renal melasma:—*a.* That it shall have commenced on the parts most exposed to light or other irritant; *b.* that it shall be most marked on the parts most abundantly supplied with pigment in a state of health, and next in degree in those most exposed to light or to irritation; *c.* that it shall be symmetrical, or nearly so; *d.* that there shall be stains on the mucous membrane of the lips; *e.* that while there shall be some patches, yet that the entire surface shall be muddy and discoloured. Cases of melasma having no connexion with the supra-renal capsules are not of very infrequent occurrence, and much care is requisite in forming an opinion. By attention to the above rules, however, we believe that mistakes might generally be avoided.

## HOSPITAL NOTES.

### CONGENITAL DIVERGENT STRABISMUS.

Like talipes equinus, although often reported so, strabismus is almost never congenital. It was a subject of conversation in the operating theatre of the Royal Ophthalmic the other day, and no one present recollected to have seen a case in which a convergent squint had been proved to have existed at the time of birth. A case was at the time under notice, in which Mr. Critchett was about to operate upon a young woman of about 19, for a severe divergent strabismus, which her father, an intelligent man, stated to have been congenital. Somewhat bearing out his statement was the fact that he had himself exactly the same form of squint. In his own case the squint had resulted from an attack of small-pox, during which the left eye (the affected one) had suffered from pustular inflammation. The deformity was very great in both patients. Mr. Critchett operated on both, in each instance dividing both external recti. In the father, after the muscles had been cut through subconjunctivally, the eyes became quite straight, but in the daughter, even after the freest division of muscle conjunctiva, and cellular tissue, they still remained divergent,

and a suture, carried over the bridge of the nose, was accordingly employed to hold them in. This result bore out the opinion as to the different nature of the disease in the two patients. In the father it was as usual a spasmodic shortening of the affected muscle, while in the daughter it was probably a congenital partial paralysis of its antagonist.

### DIABETES FOLLOWING A BLOW ON THE HEAD.

A woman recently under the care of Dr. Todd in King's College, in consequence of the effects of a blow on the head, afforded an interesting example of the occurrence of saccharine urine after cerebral concussion. She had fallen down a flight of stairs, and was admitted with numerous contusions about the scalp, and with hemiplegia and rigidity of the right side. The urine examined on the 20th day, had a specific gravity of 1021, and contained a small quantity of sugar. Subsequently the sugar was diminished to an almost imperceptible amount, and the specific gravity fell. She never recovered from the paralysis of motion, and the affected muscles wasted. Some of our readers may perchance recollect a case treated by Dr. Goolden some years ago, to which we then adverted, in which a railway stoker was struck violently on the occiput by the handle of a crane, and became diabetic during the illness which followed. Neither in him, nor in Dr. Todd's case just adverted to, was there any reason for suspecting that diabetes had been present prior to the infliction of the injury.

### UNUSUAL FORM OF PAROTID TUMOUR IN A BOY.

Mr. Wormald has under his care in St. Bartholomew's a boy of the age of 8, whose case affords an example of an unusual form of tumour at so early a period of life. The growth was of considerable size before the excision, and occupied the right parotid region. It had not as far as could be ascertained, been of congenital origin, having been noticed only for about two years. It was found in the excision to consist partly of solid fibroid material, and partly of cyst cavities containing either blood or a grumous fluid. Mr. Wormald informs us that in the microscopic examination of the interior of these cysts, (which was made at the College of Surgeons,) some spores, etc., of a vegetable growth were discovered. The examination was made within a few hours of the operation, and he therefore feels confident that these bodies must have been there while the tumour was *in situ*, and had not been accidentally conveyed there afterwards.

## Medical Times & Gazette.

SATURDAY, MAY 15.

### FREE AND SELF-SUPPORTING HOSPITALS.

OF all the noble institutions of our country there are none which shed so bright a lustre on the British character as our Charities; and our Medical Charities are peculiarly honourable to us as a nation, and as a Profession. The public generously contribute to relieve the suffering poor, while the Medical Profession expend their time, and frequently exhaust both mind and body in the divine task of healing the sick. We hail the erection and establishment of a new Hospital as a proof that we are not backward in emulating the munificence of

our ancestors—a proof that with increasing population, and augmented wealth, we are as mindful of our duties to the poor, and take as much pleasure in the benevolent task of ministering to their necessities, as any “Good Old English Gentleman, one of the olden time.”

Last week there was a meeting at Bristol for the purpose of setting a new General Hospital of 100 beds fairly under weigh; and we see with a glow of national pride that “merchant princes” still live among us. The names of Mr. George Thomas and Mr. Joseph Eaton are names common in the middle or even the lower class; yet these gentlemen are known to their townsmen as munificent philanthropists. Mr. Thomas has contributed *six thousand* pounds, and Mr. Eaton *six thousand five hundred* pounds to the new Institution, while Dr. James Fripp, formerly a Physician to the Hospital, has given upwards of £1000. By these gifts, and a noble subscription list, the new building may be opened free of debt. The people of Bristol, and the country at large, may well be proud of such a monument of benevolence.

We would also call especial attention to this meeting on account of some remarks of our valued contributor, Dr. Symonds, on the comparative claims of missionary efforts abroad and suffering poverty at home, which deserve a far wider consideration than that of the audience of the Bristol *Athenæum*. He said:—

“I see, and I see it with pride, for it redounds infinitely to the honour of this locality, that vast sums are raised annually in order to impart a purer religious faith, nay, the blessings of our dearly-prized Christianity, to the dwellers in the furthest regions of the world—to people with whom we are connected by the remotest and slightest links of human brotherhood. I find that the annual contributions to various missionary societies in this district amount to no less a sum than £7000. (Hear.) This computation does not include the Colonial, the Foreign Aid, the Jews, the Patagonian, and other less extensive missionary societies, and it is confined to missions to the heathen. Now, on looking at the report of our Royal Infirmary, I find that the annual subscriptions amount to £3054. In the report of the General Hospital I find that they amount to £772; the total amount of the two charities, £3826. I confess these numbers startle me. On the one side I see this splendid, chivalrous, truly Christian large-heartedness shown in raising £7000 annually, with the hope of converting the heathen to our holy religion—I do not ask with what degree of success, for the design and intention are sufficiently noble. (Hear.) But what shall be said, when we find that for our suffering fellow-townsmen—men, women, and children whom we see in our daily life, whose groans and sighs may be almost heard at our very doors; whose hands and feet when strong and well, are providing our daily comforts and luxuries, who have grown up around us, breathed the same air, and worshipped in the same temples—for whom every shilling spent in hospital accommodation and hospital skill and knowledge is certain to produce its full equivalent, either of cure and restoration of the capability of maintaining themselves and their families, or, at all events, of alleviation and solace—what shall be said when we find that for these our near brethren and their piteous wants, we raise annually in funds for hospital accommodation a sum not amounting to £4000? (Cheers.) I have compared and collated these numbers, thinking they might be incorrect, but the anomaly remains. We are so liberal and beneficent that we can fling our largess broadcast towards those far-off sable and tawny races, separated from us by wide tracts of ocean, and by still wider differences of interests, and habits, and feelings, hoping and desiring that they may share our spiritual blessings, and we comparatively overlook our own brethren who may be dying or suffering unalleviated miseries for lack of the help which we are so able to give them. (Cheers.) God forbid that we should restrict or lessen the other acts of beneficence, but I do wish that what is due to the Hospital wants of our poor should bear a fitting proportion. What that proportion is, it may be difficult to state in figures; but were I to attempt a numerical expression of the ratio, I should say that the claims of the heathen on us for missionary efforts are, to the claims of the poor of our own district for Hospital

help, as one to a hundred—and if you do not allow this you will admit it to be certainly not higher than one to ten. (Hear, hear.) If this be so, and if you raise £7000 annually for missionary purposes, you ought to be able and willing to raise £70,000 annually for the support of Hospitals, were so large a sum required. (Cheers.)”

We would hold up before the public the duty of supporting our Hospitals as of paramount importance, but to do this earnestly and conscientiously we must be able to state honestly, that the donations of the benevolent are really expended upon deserving objects, that their charitable efforts, made probably with some self-sacrifice and difficulty, are not abused by undeserving recipients. We must be especially careful that the proper and honourable feeling of independence of the working classes is not undermined by teaching them the first lesson of dependence upon the unearned help of others.

Now it has become notorious to the Profession, and the public are also becoming aware of the fact, that persons do obtain relief at our Medical charities whose means ought to enable them to provide Medical attendance for themselves. We have lately alluded to the effort which has been made to correct or obviate this evil by the establishment of self-supporting Dispensaries in different parts of the country, and we are happy to be able to state that a committee of earnest men is now engaged in the task of preparing a statement of the facts bearing upon the matter, for the consideration of the entire Profession. In the meantime, it may not be unacceptable to our readers if we put them in possession of information as to recent efforts to make some of our Hospitals wholly or partially self-supporting.

In a report of a ball which took place last week, in aid of the funds of the German Hospital, we find the following statement:—

“Attached to this Hospital is a sanatorium, which offers accommodation to German patients *not belonging to the lower classes*, who being unmarried or separated from their families and friends, may have a room to themselves either gratuitously or, when able, on paying a moderate remuneration to the funds of the Institution.”

Thus a system, widely extended in France and Germany, has been introduced into England; and those persons who are able to contribute towards the funds of an Hospital, have the opportunity of doing so, and are without the excuse of many of those who now absorb the contributions of the charitable in our Hospitals, on the plea that though not absolutely destitute, they are still unable to pay for board, lodging, nursing, and Medical attendance, when sickness cuts off their earnings, and know of no resource but a charity. In some of our special Hospitals and Dispensaries, the continental system has been imitated more or less closely. In the Orthopædic Hospital a bed can be obtained on payment of ten guineas. In the Skin Hospital, all the in-patients have to pay a weekly contribution. At the Central London Ophthalmic Hospital, many of the out-patients pay half-a-crown for a ticket, which entitles them to a separate waiting-room and priority of attendance. At the Blenheim-street Dispensary a penny has been collected for every attendance of a patient. There are probably other institutions in which, on true or false principles, an attempt has been made to check the system of indiscriminate relief.

We need not stop to point out the essential difference between some of these plans, and the system so ably advocated by Mr. Smith, of Southam. The one is a system of *CHEAP* PHYSIC, and the poor would certainly not be trained to habits of providence by knowing that when sick they could procure a dispensary ticket for a penny. Mr. Smith's plan really amounts to a mutual assurance society (free from the disadvantages of benefit clubs), in which the poor learn to provide against illness by a stated payment while well. Again, the plan of granting monthly tickets for half-a-crown would

probably appear not quite fair to neighbouring general practitioners.

The German Hospital and the Orthopædic are the only two we know of in which beds can be obtained on payment. The subject has attracted the attention of the Committee of the Samaritan Hospital, and has been alluded to in their report for 1867, but has not yet been carried out in practice in that Institution.

Two Institutions, however, have been established with this express object in view, both partially self-supporting. The one must have attracted the attention of our readers by the following notice, which has frequently appeared in our advertising columns :—

### Gentlewomen, during Illness, may, for

a small weekly payment, receive the comforts of a HOME, combined with the best Medical and Surgical treatment, at the Establishment, No. 1, Upper Harley-street. This Establishment, which was opened in 1850, is patronised by Her Majesty, the Bishop of London is Visitor, and it is managed personally by the Lady Caroline Garnier, the Lady Laura Palmer, Mrs. Guthrie, Mrs. Thomson Hankey, Miss Alexander, and other ladies. All information respecting it may be obtained on written or personal application to the Lady Superintendent. Subscriptions received at the Institution, and by the Treasurer, E. MARJORIBANKS, jun., Esq., 59, Strand. W. C. SPRING RICE, Honorary Secretary.

This Institution, we have reason to believe, is exceedingly well managed. Its Medical Officers are Dr. Watson, Dr. Ferguson, Dr. Bence Jones, Dr. Weber, Dr. Farre, Mr. Cæsar Hawkins, and Mr. Bowman; but as it has only lately been advertised it has not been so useful or so generally appreciated as it deserved, or as it would have been had it been better known.

Very recently another Hospital, on a somewhat similar plan, has been set on foot at Bayswater. The HOME in Harley-street is a General private Hospital, that at Bayswater is a Special private Hospital for "Surgical Diseases of Women;" rather a vague definition. But as we learn from the prospectus, lying-in cases and cases of syphilis are not admitted, it is probably meant to confine the benefits of the institution to women suffering from such diseases peculiar to their sex as admit of relief from surgical treatment. The Medical officers of this HOME are Mr. Skey, Consulting-Surgeon; Dr. Priestley, Physician; Mr. Baker Brown and Mr. Nunn, Surgeons; and Mr. Harper, Assistant-Surgeon. Four gentlemen in general practice, residing in the neighbourhood, are to act as Visiting Surgeons, in place of House-Surgeons.

This scheme has met with a great deal of opposition and some obloquy, but we really do not see any very valid objection to it. It may be said that as subscriptions are solicited to furnish the house, and £500 a-year is asked for to maintain ten beds, the patients are still recipients of charity. This is true, and it might have been well to have departed from the example set in Harley-street, and have endeavoured to make the institution entirely self-supporting, and a means of legitimate remuneration to the Medical officers, on the same plan as the private lunatic asylums, which are so useful to the public, and so profitable to a highly-respectable class of the Profession. But this would imply a high scale of charges for admission, and the object appears to be rather to help those who are willing to help themselves as far as they are able, than to provide for those who can afford the necessary expenses of a purely private establishment.

There is an objection common to these HOMES in Harley-street and Bayswater, to which really private Hospitals are not exposed. The patients, though they pay, are still to some extent recipients of charity. Their board and lodging are partly provided by the benevolence of the public, while they are attended gratuitously by the Medical officers. Here the Provident Dispensary scheme of Mr. Smith is very superior, as the Medical officers receive some remuneration for their labours; and we trust some means may be devised for extending this principle to Hospitals as well as Dispensaries. In some of the oldest of our endowed Hospitals the Medical

officers receive an annual salary; and it might surely be possible to devise some plan by which, in a self-supporting establishment, the patients might be spared the reflection that they were receiving the gratuitous services of the Medical officers. There might be a difficulty in cases where, as in the Harley-street and Bayswater "HOMES," the charitable and self-supporting systems are mixed; but this difficulty is successfully overcome by Mr. Smith in his Dispensary scheme.

The plan of purely private Hospitals is one likely to attract the attention of the Profession. The public have felt the want of such establishments; and the success which has attended hydropathic institutions has probably been owing to the absence of more orthodox residences for invalids. Since the failure of the Sanatorium in which Dr. Southwood Smith took so active a part many years ago, we have heard of nothing of the kind in London, until a Sanatorium was started at Highgate two or three years ago, although in Dublin the plan had been worked successfully. More recently, if we may judge from advertisements in the daily papers, the practice of Medical men receiving patients into their houses, and probably arranging their houses for the reception of invalids, appears to be on the increase; and we may direct attention to an establishment in Queen-square, under the superintendence of a lady who has had a large Hospital experience. This "Home for Invalids, or persons requiring care and attendance during surgical operations," has been recommended to our notice by Physicians and Surgeons of eminence who have had patients there; and we may state, after personal inspection, that any of our readers who may wish to place patients in a private house where they would be as well attended to as in any public Hospital, would do well to visit this house. "There is no Medical man connected with the house, each patient having his own Medical attendant," says the advertisement. The absence of a resident House Surgeon might be an objection in some cases where the Medical attendant lived at a distance, but this would be met in any similar institution superintended or established by one or more resident General Practitioners.

This plan is one which deserves and must receive attention; and we have no doubt that by careful consideration of details, a scheme might be perfected tending to correct existing abuses in charitable institutions—the appropriation of funds to those whose means should place them above the receipt of eleemosynary aid—and avoiding any objectionable combination of commercial speculators with professional men.

### THE WEEK.

DR. LANKESTER has just circulated his Second Annual Report to the Vestry of St. James. It is a curious circumstance, that, although he has insisted most strongly on the danger to health and life from using the waters of metropolitan surface wells as drink, and the vestry closed several of the pumps, yet they have recently ordered them to be re-opened. The quantity of putrid or putrifiable matter in the porous soil through which the rain-water soaks into these wells is so abundant, that it becomes charged with the products of the decomposition of organic matter, and may undergo a kind of fermentation, rendering it quite unfit for human consumption. The history of our cholera epidemics has shown the immense mortality which has been caused by the use of impure water; but the Vestry of St. James are wiser than their Medical officer, and think they can afford to disregard his caution. Dr. Lankester also insists very strongly upon the necessity for ventilating the sewers. He shows that disease is frequently caused by the effluvia emitted through the gully-holes and valves of the sewers into the streets. In another column some account will be found of the remarkable observations of Dr. Barker of Bedford, bearing out these recommendations

of Dr. Lankester. Among some excellent remarks on prostitution, Dr. Lankester says: "It is the systematic exclusion of this topic from public discussion that has caused it to assume its present enormous magnitude; and were the public generally acquainted with the terrible physical evils falling alike on the virtuous and the guilty, which are consequent on this state of society, the evil of which we complain would receive its most effectual check." Such reports as these from our Medical Officers of Health to the Vestries of the metropolis, must have a great influence for good; and we trust the Profession generally will support them by all the influence they can bring to bear upon the ratepayers in furthering sanitary measures. "The sanitary question is a national one and a religious one; for just as we decrease disease and death, we shall find that we increase not only the physical powers of our population, but their intellectual ability and their moral character."

The motion of Lord Ebrington and the debate it gave rise to on barrack accommodation, must do good. It has been shown that upwards of three millions have been spent in the last four years for barracks, and also that the military authorities have certainly not made the most judicious application of the funds placed at their disposal. The Sanitary Commission has shown that the faults may be traced in a great degree to the want of power in the Medical department. The suggestions of Medical officers are slighted by their military superiors; but the public will now insist that the improvements which Dr. Smith and the Department have long been fighting for, in the lodging, food, and clothing of our soldiers, shall be carried out, and that the large sums of money voted by the country shall be expended in accordance with the dictates of common sense and sanitary science.

Dr. Brown Séquard commenced a course of six lectures on Wednesday in the Anatomical Theatre of St. Bartholomew's Hospital, on the Physiology of the Nervous System. His first lecture was a very interesting one on the transmission of sensitive impressions to the brain. The course will be concluded next week by lectures on Monday, Wednesday, and Friday, commencing at half-past 12 o'clock. The opportunity of attending these lectures should not be overlooked by physiologists.

The Irish Poor-law Commissioners have reported a considerable decrease in the number of vaccinations in Ireland in 1857 as compared with 1856. They have exposed the danger to human life from the present state of the law, and Lord Naas has stated in the House of Commons that he hopes to introduce a Bill this session for amending the law.

The deputation to the Poor-law Board on the subject of the grievances of Poor-law Medical Officers, was a very influential one. About sixty gentlemen attended, including twenty members of Parliament. The result may also be looked upon as satisfactory, for Mr. Estcourt, the new president, promised to lay a bill on the table of the House of Commons before the close of the session, so that during the recess the country would have time to consider it, before it is discussed in Parliament next session.

Lord Elcho's Bill, as was expected, did not come on for the second reading on Wednesday; so that, as we stated as probable some weeks ago, the first debate on Medical Reform will take place on Mr. Cowper's Bill. A deputation is to wait on Mr. Walpole at the Home Office this day, from the

Reform Committee of the British Medical Association. A sort of general invitation has been issued to Medical practitioners to accompany the deputation; and it is to be hoped that the Home Secretary will gain some information on the subject from the speakers, though in the present state of political affairs in the Houses of Parliament, the Medical Reform Bills seem in danger of being postponed *sine die*.

The Rev. W. Newnham was elected Chaplain at St. Mary's Hospital, on Monday, after a severely contested election, there having been more than forty candidates in the field. The Medical officers were delighted that so eligible a candidate should have been a son of the esteemed and greatly respected Newnham, of Farnham.

The meeting at the Freemasons' Tavern, on Tuesday, of the supporters of the Medical Benevolent College was a very numerous and exciting one. Mr. Labouchere was in the chair. The party in favour of a postponement of the adoption of the report numbered 45. So many important questions were raised for discussion, affecting so materially the future welfare of the College, that we must defer until next week our comments upon them, and the report of the meeting.

Mr. Love, of Burton-street, Eaton-square, has sent us the particulars of a case which should put the public on their guard against the danger of sleeping without removing any false teeth they may wear. Last week he was called to a gentleman, 26 years of age, who was awakened with violent pain in the throat, and stated that he had swallowed two metallic teeth, with a plate of platina to which they were fixed. Mr. Love found them so far down as to be out of reach, so he pushed them into the stomach with a probang. This was followed by immediate relief, but the pain returned in the course of the day, continued to increase, was followed by hematemesis, and the patient died on the sixth day. It is curious that while the teeth were in the œsophagus the pain extended from the neck down the arms to the fingers, but when they were in the stomach it only extended to the elbows. This case, and similar ones, which have been recorded in America, and are reported in this journal, should teach people who wear false teeth to remove them before going to bed.

Dr. Lever mentioned a singular fact at the last meeting of the Hunterian Society. He had seen two women lately who had died in the eighth month of pregnancy. The children were both alive after the death of the mothers. Both fathers refused permission to allow removal of the live children from the dead mother by the Cæsarean section. This raises some singular questions both in law and morals. Husbands have generally been anxious for the operation being performed, because if the child came into the world living, they acquired a legal right for life to the wife's real estate. We may suppose a case in which property is settled on a child of a female (if born alive), so that by its death it would pass from the husband to the wife's next of kin,—while if there were no child born or extracted alive, the husband would enjoy it under a deed. Or the husband may not wish to have the charge of a living child. No such point having been raised for decision in a court of law, Dr. Lever consulted Dr. Taylor, who said that in such a case he did not think a Medical man would have a *legal* right to deal with the dead body of the wife except by *consent of the husband*. The object of the operation is good, but the end does not, in law, justify the means. As a matter of dry law, a husband

might perhaps be legally justified in refusing to allow an accoucheur to perform the operation, although morally speaking, his conduct would not be justifiable. He might object to have his wife's dead body interfered with, even for what, professionally speaking, might appear to be a good purpose. There might be cases in which such a power as that claimed by Dr. Lever would be grossly abused; and it would, at any rate, be a shock to public feeling that any Medical man on his own statements of the condition of things, should have the power of opening the body of the dead wife, against the wishes and feelings of the husband. A child in utero is not a living child in law; consequently, legally speaking, the non-extraction of it by operation would not be homicide in any sense. Women are constantly acquitted of the murder of children, because it cannot be found medically that the child had come *entirely into the world living*, when the murderous violence was inflicted. This is very absurd, and requires altering; still it is the state of the law. Had Dr. Lever extracted one of these children in spite of the refusal of the husband, he would not have been liable to an action, but to an indictment under the Anatomy Act, or at common law for an offence "*contra bonos mores*." His answer might be, he wished to bring into the world a living child; but we doubt whether this would be held a legal justification for the act, since the law does not look to consequences, but judges of acts by rigorous rules.

We observe, with great regret, that the Poor-law Board has completed the series of persecutions to which Mr. Symes, of Bridgewater, has been subjected by the local Board of Guardians, by requesting that gentleman to resign his office. Whether he will do so remains to be seen; and we shall be curious to know what ulterior steps may be taken in the case of his refusal. If the extreme severity of the Poor-law Board against Poor-law Medical Officers who are supposed to be guilty of neglect of duty were compensated by a corresponding anxiety on the part of the Board to defend those Medical Officers who are ill-used by the local Boards, perhaps we should not have very much reason to complain, and we might palliate the harsh judgments of the Whitehall authorities on the ground of the necessity of dispensing equal justice; but we fear that we are not overstating the case when we affirm that in nearly all cases of disagreement between the local Boards and the Union Medical Officers, the latter are denied all redress. Thus the power undoubtedly possessed by the superior Board to restrain the harshness and tyranny of the local cliques, becomes virtually a dead letter; and the Medical Officer, ground down to the most paltry remuneration, is expected to discharge the most onerous duties, while any neglect, or supposed neglect in their performance, is visited by the most terrible retribution, such as should only be inflicted for the most gross moral delinquency. To expect a man to work almost for nothing, and to be punished when he does not work enough, appears to us to be the extreme of severity and injustice.

## THE SEWAGE OF TOWNS.

THE preliminary report of the Royal Commission appointed to inquire into the best mode of distributing the sewage of towns has been laid on the table of the House of Commons.

The Commissioners state that they have paid particular attention to the case of London, and have appended the outline of a plan, which is altogether new, for dealing with the sewage of the metropolis. This is the leading feature of the report; but the Commissioners first describe the nature of the inquiries that have led to the conclusions at which they have arrived.

It is observed that the abolition of cesspools and the general

adoption of waterclosets having rendered necessary a more extended system of sewers of greater capacity, the discharge of so large a body of sewage into town-rivers must be productive of nuisance and disease among the inhabitants upon the banks. The Thames, before it reaches the point from which the water-supply of London is at present derived, receives the refuse of districts containing upwards of 700,000 persons. Not only is the water, when polluted with sewage matter, eminently unfit for human consumption, but it destroys the fish, as was the case at Leicester, until the liquid sewage was rendered innocuous by chymical processes, since which time the fish have again appeared. In the prosecution of their inquiries the Commissioners have visited Tottenham, Croydon, Leicester, and Cheltenham, in which towns works are carried on for the purification of the sewage; also, Rugby, Watford, Rusholme, Mansfield, and Edinburgh, where sewage is applied in a liquid state to the adjacent lands, besides several farms over which manure is used in a similar manner; and a deputation visited Milan to observe the sewage manuring processes adopted in the neighbourhood of that city. The results have been found so satisfactory, that in some cases very valuable meadows have been created from that which was formerly mere barren sea-sand; while the absorption is so rapid, that no offensiveness is appreciable, even in hot weather, within five minutes after the application of the liquid.

For large towns the Commissioners are of opinion that the precipitation process is the best, allowing the water after purification to pass off, and leaving the thick "sludge" alone to be used for manuring purposes. This, therefore, is the plan which they propose for London.

Convinced by the representations of Mr. Goldsworthy Gurney that the mere diversion of the sewage will not purify the Thames from its present foul condition, the effect of past accumulations, the Commissioners recommend the immediate execution of the embankment scheme propounded by the Metropolis Improvement Commission of 1844. Advanced terraces being constructed, continuous on the surface, but affording convenient entrances to inner basins for the wharfs above London-bridge, reservoirs are to be formed in the embankments adjacent to the mouths of the existing sewers, into which all the sewage is to be received and deodorized, and from which—the purified water being first allowed to flow into the river—the precipitated matter will be pumped into the country or to the sea. The reservoirs and apparatus are to be beneath the surface, and consequently invisible; so that no nuisance whatever can be apprehended.

The subsidiary parts of the scheme are the adornment of the river, the relief of the streets by the terrace carriage ways between London and Westminster, and the connexion by railroad of the existing termini on the southern shore. The cost of the entire works is estimated at £3,250,000, exclusive of any approaches which may be formed in connexion with the new thoroughfares.

The report extends to 35 octavo pages, exclusive of an appendix, and is signed,—

## DIPHTHERIA.

THE following remarks from the last quarterly return of the Registrar-General are important:—

A disease, which is not new, but has been described afresh in France, has been fatal in several districts. It has been called "throat disease" in some of the returns, and from its having attacked English visitors in Boulogne the name of that town has been occasionally employed to qualify the affection. Diphtheria, its name in the statistical nosology, is adopted from the French writer who described the disease under the name of *diphtherie*, in reference to the characteristic membranous exudation in the throat. (a) The termination "*itis*," as in gastritis, is used in medical language to designate pure inflammation of the organ, which the root of the word

(a) *Diphthera*—*διφθέρα*—a prepared hide, leather. *διφθέρα* were used for writing-on in the east, like vellum or parchment. (Liddell and Scott.)

expresses; hence *ia* has been substituted for *ite*, the French form of "*itis*," as this cannot with any propriety be placed after *diphtheria*, designating a product of disease, and not an organ of the body.

No notice has been taken of the disease by the registrars either in the country north of Staffordshire or in Wales; and it has probably not prevailed there epidemically to any great extent. It is, however, allied to one of the forms of scarlatina, and is still confounded with that disease, with croup, or with quinsy, by some practitioners.

Diphtheria, like Asiatic cholera, is probably only a more intense form of an old disease; but new intense spreading forms of disease deserve close attention, for with the increasing density of population, the intimate connexions between England and every unhealthy climate of the world, and the slow progress of sanitary improvement, we cannot consider ourselves absolutely safe from an eruption of some epidemics, which, like their predecessors, may open a new chapter not only of medical but of national history; for Niebuhr acutely remarks, that the great epochs of history are marked out by pestilences.

Epidemics, like new varieties of animals, spring up under favourable circumstances. Each epidemic form has its congenial climate. The cholera epidemic is bred on the delta of the Ganges; yellow fever on the banks of the Mississippi; plague around the Nile in Lower Egypt; typhus in our towns; ague in our marshes; diphtheria, according to the popular theory in France—where the conditions are more favourable, on the whole, than they are in England—to the diffusion of putrid effluvia over the fauces.

Every Englishman admires the works of art, the picture galleries, the houses, the furniture, the cultivated personal tastes which surround him on every side in Paris, or on a small scale in Boulogne. He admires some of these objects every day, others every week; but has every day to give up his admiration at the door of that inscrutable cabinet where the light of French refinement never comes; where his throat is assailed by the poisonous distillations that engender disease, and explode, if you count well the victims, with much more fatal consequences than gunpowder or even than fulminating quicksilver. That men should lock up jewels in cabinets, keep their larders full of delicacies, or stock their cellars with wine is natural; but it is a singular absurdity in civilized men to attempt to hoard for years this volatile essence, which bursts its chains, and, like an unclean spirit, enters not only every apartment in the house, but every channel of access to the living chambers of the body, leaving at times such traces of its passage as diphtheria in the throat. The disease once generated, wanders abroad, and destroys life under circumstances quite different from those in which it was born; but impurity is always its natural ally.

The Scotch threw these matters into the streets, and justly incurred the censure of the fastidious. In London, and even in the country mansions of England, retreats still exist which may rival the French magazines of impurity; but it has of recent years been the practice to throw the guano compounds of London, with water, into the sewers; which, though not constructed for the reception of such matters, and consequently suffering their volatile principles to escape into the streets, convey a portion of their elements to the Thames, and commit them to its flood of tidal waters.

Dr. Barker has recently performed an ingenious series of experiments on animals, to determine the effects of each of the noxious principles which arise from cesspools. He placed the animals in a close chamber by a cesspool, with which a tube opening into the chamber communicated; and a lamp was arranged so as to draw a current of cesspool air steadily over the creature's inside. With a pair of bellows Dr. Barker could draw the air from the chamber. A young dog in half an hour "became very uneasy and restless; he vomited, and had a distinct rigor, and in the course of a day was exhausted. When he was removed he soon recovered." "Another dog was subjected to the cesspool air during twelve days;" in the first seven days he underwent a series of sufferings, not unlike the symptoms of the disease of children in hot weather; on the ninth he was "very ill and miserable." After he was liberated, on the twelfth day, he remained "very thin and weak for six weeks." Dr. Barker then continued his experiments on the effects of definite doses of the gases in the sewers, and killed or poisoned several sparrows, linnets, jackdaws, and dogs.

Thus Dr. Barker has, for our instruction, imitated on a small scale, and on a few of the inferior animals, the vast experiment which is constantly going on, and destroys thousands of men, women, and children all over England. Instead of a few animals in a close chamber, more than two millions of people live in London over sewers and cesspools. The poison is generated in every house; it is distributed conveniently along all the lines of road, so as to throw up its vapours into the mouths, throats, and lungs of the people through innumerable gully-holes, which are either left untrapped, or trapped imperfectly, in order that the poisonous gases might escape. A variation in the pressure of the atmosphere draws up the stinking air from the sewers, like Dr. Barker's bellows. All the details of the experiment were as carefully contrived by the engineers of the old sewers' commissioners as if they were constructing an apparatus for passing currents of poisonous airs steadily over the people of London, with a view, like Dr. Barker, to ascertain their exact effects. The engineers of the new Board of Works have endeavoured to keep the apparatus in order.

It is now time that this cruel experiment should cease. Last year, when no epidemic prevailed, not less than 14,795 unnatural deaths were registered in London. This was the aggregate effect of the impure airs, and of other sanitary defects.

Will the London Board of Works stop the experiment? Are they, like Dr. Barker, convinced and satisfied? Will they bring their common sense to bear on this question? Gases are constantly generated in the sewers and cesspools, and these gases will escape. Their elasticity carries them—and perhaps still more poisonous organic compounds—through the gully-holes, so long as there is no other outlet. But what can be an easier engineering problem than to discharge into the atmosphere the sewer gases, through pipes running up, and at least as high as the chimneys? This is in partial operation, and if made universal would be a mitigation of the evil. There are many ways of getting entirely rid of these gases, and why should not the inexpensive work be at once done?

The sweet odours that enter the country are taxed; and every one has witnessed the admirable zeal of her Majesty's customs' officers in their searches for eau de Cologne. If a tax could be levied upon odours of another description, bearing some proportion to the evil they do, it would be much more productive; and if it were levied through the agency of the Board of works in London, and the Sewers Commissions elsewhere it might be more beneficial, as they would undoubtedly find it economical to substitute fountains of rose-water for their present gully-holes.

## REVIEWS.

*A Treatise on the Employment of the Speculum in the Diagnosis and Treatment of Uterine Diseases; with Three Hundred Cases.* By ROBERT LEE, M.D. F.R.S., Obstetric Physician to St. George's Hospital. Pp. 132. London: 1858.

To expose the abuses of the Speculum is a favourite pursuit with Dr. Robert Lee; and in his present work, the substance of which has already appeared in the *Transactions of the Medico-Chirurgical Society*, he gives us the history of three hundred cases, in which the introduction of the instrument has been unnecessary, or has been attended with positive mischief. If there be any enthusiastic admirers of the speculum who unduly extol its advantages in practice, they may derive some useful hints from the perusal of Dr. Lee's pages, in which the other side of the question is warmly advocated. "The speculum," says Dr. Lee, "emanated from the syphilitic wards of the Hospitals of Paris, and it would have been better for the women of England had its use been confined to those institutions." It is quite unnecessary to point out that abuse and use may be, but ought not to be, confounded.

*Transactions of the Odontological Society of London, 1856-57.* London: 1858. 8vo, pp. 154.

The first volume of the *Transactions of the Odontological Society* is highly creditable to the distinguished dentists who are members of the Society. It contains the President's address at the first meeting of the Society; a number of papers of great

interest to scientific and practical dentists, by Messrs. Rogers, Bate, Tomes, Shelley, Maclean, Barrett, Robertson, Owen, and Jacob; and a paper on the Surgical and Mechanical treatment of Cleft Palate, by Mr. Sercombe, which is also important to the Surgeon. Mr. Sercombe shows that fissure of the soft palate may be remedied by simple mechanical contrivance. Two pieces of vulcanized india-rubber are fixed upon a gold plate fitted to the hard palate and upper teeth. This apparatus is simple, easily constructed, and in cases narrated gave the patients the power of distinct articulation. The results of a plastic operation are, however, so satisfactory, that it is only in exceptional cases this contrivance is likely to be adopted. Fissure of the hard palate, on the other hand, is a condition, the treatment of which the Surgeon is bound very frequently to leave to the dentist; and Mr. Sercombe shows that the cases most difficult to the Surgeon are the easiest to the dentist, and that mechanical treatment is not only safe and painless, but effectual.

*On Dislocations and Fractures. Fasciculus IV.* By JOSEPH MACLISE, F.R.C.S. London: 1858.

THIS Fasciculus contains four plates, representing dislocations of the humerus, fracture of its neck, and some remarkably good illustrations of the mechanism and dislocations of the elbow-joint. The freedom and general excellence of the drawing are well maintained as the work proceeds.

*Handbook of Chemistry, Theoretical, Practical, and Technical.* By F. A. ABEL and C. L. BLOXAM. Second Edition. London: 1858. 8vo, pp. 785.

NEARLY five years have elapsed since the first edition of this work appeared. The additional experience of the authors, and the recent researches of Continental chemists, have been so employed as to make this Handbook thoroughly deserving of the confidence of the Student of Chemistry. The general plan of the work is maintained, and many new illustrations have been added to assist the description of the processes and manipulations recommended by the authors.

*Fishes and Fishing. Artificial Breeding of Fish, Anatomy of their Senses, their Loves, Passions, and Intellects. With Illustrative Facts.* By W. WRIGHT, Esq., Surgeon-Aurist to Her late Majesty Queen Charlotte, etc. London: 1858. Small 8vo, pp. 384.

Mr. Wright's aural practice in St. James's has not prevented him from obtaining a position among the "brethren of the Angle." During many years he has entered in a book the result of his own observations, and such facts as he could thoroughly depend on. Arranged in the work before us, they form a very readable and amusing book, and are really useful to the Londoner whose angling propensities must be indulged within a reasonable distance of the sound of Bow bell.

*The Illustrated Handbook of British Plants.* By A. IRVING, F.B.S. London: 1858. 8vo, pp. 480.

THIS book is got up in a cheap form, but it is not less useful as a help to the student of British Plants. While the phraseology is simplified, the descriptions are rather scientific than popular; and the man who finds a plant, and wants to know what it is, will find the Illustrated Handbook a very useful companion.

*Algiers in 1857: its Accessibility, Climate, and Resources, described with especial reference to English Invalids.* By the Rev. E. W. L. DAVIS, M.A. London: 1858. 8vo. Pp. 163.

THIS work really contains what its title leads us to expect. The hotels and lodgings, the food and climate, the dress, the Medical men and chemists, the suburbs and scenery, rides and recreations, and the society of Algiers, are described in a lively entertaining manner, making six chapters of very pleasant reading for all, and likely to be especially useful to the Medical man who thinks of sending patients to a warm climate.

*Memorandum of Improvements suggested in the Medical Service of the Army; with a Description and Drawings of a New Plan of Equipment for the Medical Staff Corps; accompanied with some Remarks upon the Education, Duties, and Position of the Medical Officer.* By GEORGE BEDFORD, late Acting Assistant-Surgeon of the 58th Regt. London: 1858.

IN this pamphlet Mr. Bedford offers some useful suggestions for the transport of the sick and wounded from the field of battle, and for the more prompt administration of Medical and Surgical aid to the sick and wounded. He also claims for the Medical officers of the Army more substantial rank and pay, and more authority than they now possess. He exposes with considerable force the hardships to which they are now exposed, and the comparative neglect with which they are treated by commanding officers even in times of war and pestilence.

## PROGRESS OF MEDICAL SCIENCE.

### Selections from Foreign Journals.

#### STRICTURE OF THE ŒSOPHAGUS TREATED BY CATHETERISM.

By Dr. LOTZBECK.

A healthy boy, 5½ years old, swallowed by mistake, 10 June, 1856, some sulphuric acid. He screamed out from the pain, and fell upon the ground. Oil and lime-water were given, and vomiting frequently occurred. For the next five days he could only take a few drops of fluid, and during the next eight weeks his nutriment consisted solely in tepid milk, the greater portion of which he latterly rejected, so that it often happened that he passed three or four days without anything being retained in the stomach. This state of things, with alternate slight improvement and falling off again, continued for nearly four months longer, the child becoming low, thin, and dull, though not to the extent so great a privation of food might have led to the expectation of. From the 20th to the 28th January, however, not a drop of fluid, in spite of the most powerful and urgent efforts, could be swallowed, and the patient became now completely emaciated. On the 29th, he was able to take some milk again; but on the 30th commenced another period, wherein this became impossible, and the child's death was daily expected. As a last resource, an attempt was made to pass an elastic catheter, and although this did not penetrate far, the patient was enabled to swallow better after the trial had been made. The procedure was repeated whenever deglutition became absolutely impeded, and in this way some nutriment was conveyed. Things were in this state, when on 21st March he was brought to Professor Bruns' Clinique at Tübingen, in a state of the extreme emaciation and debility. Examination with an elastic catheter (No. 3 of Luer's scale) discovered an easily overcome obstacle at the lower end of the upper third of the Œsophagus, while in the middle of the lower third a thick, firm, ring-formed stricture existed, which only allowed the catheter to pass after very careful manipulation. Having done so, it easily reached the stomach; and in future it was introduced twice a-day, and allowed to remain from ten to fifteen minutes. It induced much retching; but after it had been passed five or six times, milk could be much easier swallowed, and did not induce vomiting. The size of the catheter was gradually increased, so that after fourteen days one of five and a-half millim. diameter (No. 8) could be easily passed. The improvement in swallowing was quite surprising, the patient being able to take small portions of solid food without difficulty or vomiting. The size of the catheter and the duration of its application, continued to be increased; and after four weeks' treatment the lad was discharged, being able to swallow all kinds of food, even dry bread, without difficulty. Seen in November he continued perfectly well. —*Deutsche Klinik*, 1857, No. 50.

#### RECOVERY OF AN INFANT AFTER A LARGE DOSE OF OPIUM.

Dr. Chamberlain relates the case of an infant only six days old, to whom a nurse administered a powder intended for the

mother, and containing from one and a half to two grains of opium. He saw the child two hours afterwards, and was told it was dead; in fact, respiration was suspended, the face and lips were livid, and the pupils contracted, the infant being in a state of complete asphyxia. The pulse was found slow and irregular. Artificial respiration was resorted to, and after ten minutes the pulse became more distinct and regular, and the leaden features were partially bleached. Thus encouraged, the artificial respiration was continued, accompanied by the external application of heat and rubefacients, and enemata of brandy and turpentine. "At the expiration of half an hour, while suspending the artificial respiration for the purpose of rest, a sudden, spasmodic inflation of the lungs occurred, succeeded by an apparently perfect quiescence of the respiratory muscles, attended by an increasing lividity of the face and lips, and a more laborious and irregular pulse. In from three to four minutes the same phenomenon was repeated, when the lungs were again set in motion by external aid, which was continued with occasional interruptions, for the space of more than three hours, before continuous unaided respiration was sustained. At the close of the second hour, it was observed that the above-mentioned spasmodic expansion of the lungs would occur at irregular intervals of one or two minutes, succeeded by perfect rest, except the slow and imperceptible contraction of the lungs, as the air gradually oozed out from their cells. At the close of the third hour, the respirations were more regular and uninterrupted, and repeated about twice in a minute. The artificial aids were withheld, the external agents continued, broth was added to the injections, and, to one of them, castor oil, which was followed by a copious dejection. But it was not until ten hours had elapsed, that deglutition could be excited. Tincture of belladonna (!) was subsequently given, with no perceptible effect. In twenty-four hours, scarcely a trace of the effects of the poison was observable." There were no convulsions, although the muscles were for most of the time in a state of tonic rigidity.—*Boston Journal*, vol. lvii, p. 357.

## EXCERPTA MINORA.

*Treatment of Croup.*—Dr. Mayer having observed the great efficacy of glycerine in softening the tenacious and dried plugs formed in the nasal fossæ in ozenoid disease, was induced to try the same application in Croup, and the results thus far are satisfactory. It is sufficient to bring the substance in contact with or near the rima glottidis to secure its getting access to the larynx. He only employs it as an adjunct to other means, and for the purpose of effecting the breaking up and consequent expulsion of the false membranes. Dr. Shelton believes he has derived some advantage from the application of the following ointment every two hours, to the sound skin over the trachea.  $\beta$ . Ext. belladon. 3ij.; ung. hydr. mit. 3vj.m. With this any other of the ordinary remedies may be conjoined.—*Americ. Journ. Med. Sc.*, April, Pp. 338, 340.

*Absence of Urea and Uric Acid in Urine in Yellow Fever.*—Dr. Porcher states that careful microscopic and chemical examination of the urine during the whole course of an epidemic of yellow fever, occurring in Charleston, in 1856, proved the constant absence of urea and uric acid. He attributes to this failure of elimination some of the most dangerous symptoms of the disease, as the coma and other indications of torpor of the brain in the latter stages.—*Ibid.* p. 570.

*Creosote in Dysentery.*—Dr. Elmer found in an epidemic of a very malignant and fatal type, and which resisted ordinary treatment, creosote, given in doses of two drops every two hours in mucilage, arrested the disease.—*Ibid.*

*Prolapsus of the Funis.*—Dr. Thomas, in a paper recently read at the New York Academy of Medicine, recommends that the woman should be placed on her hands and knees, with her face and chest resting upon the bed. His rules are: 1. If the prolapsus is detected before the waters are discharged, this is all the treatment that should be adopted. 2. Should the waters have flown away and left the cord below the head, place the woman in the position, and return it either with the hand or a *porte-cordon*, formed of a gum-elastic catheter with a tape passed through it. No manipulations should be commenced until she is placed in position.—*Ibid.*

*Applications for Chilblains.*—1. Powdered borate of soda 10, and pure glycerine 10 parts, ess. lavender, etc., q. s. Signor Ruspini recommends this to parents as highly useful, applying it every evening to the feet when chilblains are even

threatened. He has also found the application useful for the removal of freckles in hot weather. 2. Collodion 30, Venice turpentine 12, and castor oil 6 parts. These are to be intimately blended by aid of a gentle heat.—*Omodei Annali*, vol. clxiii, p. 200.

*Sulphate of Iron and Glycerine in Erysipelas.*—Very finely powdered sulphate of iron 4, and pure glycerine 30 parts. In summer the solution may be effected at the ordinary temperature; but in winter warmth is required. The mixture should be applied upon a small sponge or linen; and, when desired, it may be cleaned off with a little tepid water.—*Ibid.* p. 199.

*Salt in Epistaxis.*—Dr. Morris reports a case of obstinate epistaxis which yielded promptly to the use of common salt, taken into the mouth in doses of a teaspoonful.—*American Journ. Med. Sc.*, April, p. 390.

*Successful Turning after the Death of the Mother.*—The mother died suddenly during labour, and forty minutes elapsed before Dr. Thornton arrived. He found that the membranes had been ruptured, and that the vertex presented at the inferior strait of the pelvis. He turned the child at once, and some slight delay attended the delivery of the head, so that forty-five minutes elapsed after the last expiration of the mother before the extraction was completed. The child was still-born, but was brought to by the diligent application of Marshall Hall's method.—*Ibid.* p. 569.

## GENERAL CORRESPONDENCE.

## ENCOURAGEMENT OF HOMŒOPATHY.

LETTER FROM J. KING SAMPSON, AND G. A. K. LAKE, ESQS.

[To the Editor of the Medical Times and Gazette.]

SIR,—The following resolution was passed by the Southampton Medical Society, on 4th December, 1856:—

"That a Homœopathic practitioner should not be met in consultation by a member of this society, under any circumstances."

If our decision can in any way promote the cause you have lately so ably advocated, we shall feel obliged if you will give it insertion in your journal.

We are, &amp;c.

Southampton, May 6, 1858.

J. KING SAMPSON,  
G. A. K. LAKE,  
Honorary Secretaries.

## THE CONSTANT GALVANIC CURRENT.

LETTER FROM J. ALTHAUS, M.D.

[To the Editor of the Medical Times and Gazette.]

SIR,—In your last impression, Dr. Remak, of Berlin, has published a rather startling account on the therapeutical action of the "constant galvanic current," which, according to him, is one of the most wonderful agents that has ever been heard of, as we are able by means of it, not only to cure or improve rheumatism, hemiplegia, paraplegia, atrophy, chorea, etc. etc.; but also inflammatory states of the spinal marrow, which sometimes precede atrophy of this organ. I do not think you and your readers will expect that a serious answer should be given to such assertions; nor will such answer be necessary to Dr. Remak's statement of what he calls the fact, "that the current of induction cannot be applied to the living body without shocks, and that these shocks have a weakening effect," as the daily experience of all other electricians but Dr. Remak proves that, on the contrary, the nutrition and strength of the muscles are increased by the application of the current of induction.

During a visit to France, Dr. Remak made some experiments before colleagues in Paris, as he narrates in the paper that was published in your last impression. As to the results of those experiments, it may be just as well to quote the report on them of Dr. Déchambre, whose impartiality has never been questioned, in the *Gazette hebdomadaire*:—

"From four subjects galvanized under our eyes, two were in such a condition, that we should have been much surprised to see any improvement produced in some moments. The first was a case of general progressive paralysis, espe-

cially pronounced in the upper extremities. The muscles of the shoulder were electrified, but the movement of elevation of the arm has thereby not become easier. The second had a treble lateral curvature of the spine, in consequence of an inclination of the pelvis to the left side, resulting itself from sciatica. It was tried to redress the middle and inferior curvature by the excitation of the muscles in the convexity; but, without any appreciable result. The two other cases seemed to offer more chances; for in the one there was an incomplete paralysis of the deltoid, in consequence of a contusion in a very young man; in the other paralysis of the extensors of the hand ascribed to a cause of the same kind; but here also the effect was none."

We may therefore yet question a little the "astonishing successes," obtained by the "discovery" of Dr. Remak, a discovery which was made and applied a long time before him, by Nobili, Matteucci, and Becquerel. I am, &c.

J. ALTHAUS, M.D.

2, Manchester-street, May 8, 1858.

### MEDICAL BARONETS AND KNIGHTS.

LETTER FROM H. L. MAYSMOR, ESQ.

[To the Editor of the Medical Times and Gazette.]

SIR,—Would you be kind enough, when space permits, to insert the following names of Medical Baronets and Knights, which I have found since the publication of my first list in June 1857.

I have placed an asterisk to those names which I consider as doubtful, that is, I am not *positive* that they were Medical men; but have reasons for thinking they were.

I am, &c.

H. L. MAYSMOR.

Springfield Lodge, Park Villa East, Regent's-park,  
May 3, 1858.

Alley, Sir George, living in 1810. Dead.

Atkins, Sir Henry, M.D., Physician to James 1st.

Barry, Sir Nathaniel, M.D. Dead.

Dun, Sir Patrick, M.D. Dead.

Elliot, Sir John. Died 1787.

Fordyce, Sir William, M.D. Born 1724; died 1792.

Hamilton, Sir David, living in 1737. Dead.

Helwig, Sir John Otto, Bart. Died 1678; created a baronet by Charles II. Foreigner.

Nay, Sir James, M.D. Died 1810.

Pegge, Sir Christopher, Knt., Reader in Anatomy at Oxford. Dead.

Silvester, Sir John Baptista, M.D., Knt., L.R.C.P.; living in 1787. Dead.

Talbot, Sir Robert, Knt. Died 1681; Physician to Charles II.

Wellwood, Sir Thomas, Knt. M.D. Born 1652; died 1716. One of the Royal Physicians to William III. for Scotland.

\*Paxton, Sir William.

\*Franklin, Sir William.

\*Prout, Sir William, Knt. (M.D.?)

\*Scott, Sir Robert.

\*Doyle, Sir John.

\*Johnson, Sir William.

### POISONING BY LAUDANUM.

LETTER FROM C. F. CLOUGH, ESQ.

[To the Editor of the Medical Times and Gazette.]

SIR,—I beg to inclose you the following extract, taken from the *Doncaster, Nottingham, and Lincoln Gazette* of April 30:—  
"DEATH FROM LAUDANUM, ADMINISTERED BY MISTAKE.—An inquest was held at Mirfield on Saturday last, by Mr. Taylor, coroner for the honour of Pontefract, on the body of a boy named Albert Bottomely Farnall. He had been taken ill on the day previous, and a neighbour had advised his mother to give him some paregoric. The mother remembered that a young woman who lodged with her had been taking some medicine of that kind, and she went up to her room to get it. The young woman was out; but on the mantel-shelf were two bottles, one empty, and the other containing some liquid.

She gave the boy some of this. He almost immediately fell asleep. In about an hour he began to moan in his sleep, and soon afterwards died. In the course of the evidence, it appeared that the young woman had taken all the paregoric, and what was left in the other bottle was laudanum.—Verdict, 'Died from laudanum, administered by mistake.'"

Really, Sir, I think that when such glaring facts as these come before the public eye, it is time that our Legislature should adopt some measures to put down this awful sacrifice of human life. Such cases are occurring weekly. That a shopkeeper should be allowed to vend so deadly a poison as laudanum, as he would sell an ounce of salts, is a monstrous shame, and shows the disgraceful state of our law with regard to the sale of poisons. Here is a woman who goes to a shop—buys a poisonous quantity of laudanum for her own use—it is carelessly left lying with other bottles on a chimney-piece. A woman, ignorant of its effects, goes in and takes it away—gives her boy a dose which kills him. An inquest is held—verdict, "Died from laudanum, administered by mistake;" and there the matter ends, and the shopkeeper is allowed to go on dealing out the deadly dose as before.

From the same newspaper I enclose another extract. "The Isle" being the "Isle of Axholme," in Lincolnshire.

"THE ISLE.—Baneful as are the results of poisons, intentionally and accidentally taken, the secret and insidious habit of opium-eating is more destructive of life and more injurious to each succeeding generation. This district, we regret to say, is not exempt from the evil. The effects are visible upon the 'human face divine' of many of her Majesty's liege subjects. There ought surely to be a check to the sale of this and other deadly narcotics, as well as on the adulteration of any other articles with similar ingredients. It is the duty of Government to protect the health and lives of the people, and to do all that is practicable in order to raise their moral, physical, and intellectual condition, without regard to any financial gain or loss. Opium in its different forms is a mighty drawback in these respects, and ought to be placed in the category of poisons. An entry of the name of the purchaser and for what purpose required ought to be made by the retailer, and be open to inspection. We verily believe that this would operate as a check upon the sale and consumption of this life-destroying, and, we fear, increasing evil."

Here is a small island where the sale of opium is allowed to go on with impunity, and without any attempt being made to check the evil. I trouble you with this last extract, as I think it contains some very proper suggestions for trying to abate this awfully serious and increasing crime.

Laws rigid enough are enforced to punish the man who kills a paltry partridge without a licence, yet there is no law to prevent the shopkeeper from poisoning a precious human life.

I am, &c.

CHARLES FREDERICK CLOUGH.

Eastern Dispensary, London, May 4, 1858.

### REPORTS OF SOCIETIES.

#### ROYAL INSTITUTION.

#### ON PLANTS AS THE SOURCE OF FOOD TO MAN.

Dr. Lankester is now delivering a course of lectures on the "Vegetable Kingdom in Relation to the Life of Man," at the Royal Institution. The first lecture was delivered Saturday, April 17. In his opening remarks, he pointed out the dependence of man on the vegetable kingdom for the supply of materials for the arts and manufactures, medicines and food. It was to the latter as supplied by plants that he wished more particularly to direct attention in this course of lectures. He then drew attention to the composition of the tissues of the human body, and showed that the principal elements were carbon, hydrogen, oxygen, and nitrogen. These elements during life were constantly entering into new combinations, and the processes of life were attended with so rapid a loss that a man sitting in a balance chair might estimate his waste by the hour, by the loss of carbon alone during respiration. The elements thus lost were supplied by food. Although man ate animal food, the animals he fed on obtained their tissues

from vegetable substances. The plant was the ultimate depository of food for both man and animals. The vegetable kingdom obtained its food from the mineral, and the great sources of the organic elements to plants were water, carbonic acid, nitric acid, and ammonia. The sources of these compounds were examined, and the great source of the increase of carbon, hydrogen, oxygen, and nitrogen, as embodied in man and the domestic animals, as compared with the earlier periods of their history, traced to the constant evolution of carbonic acid and ammonia from volcanoes, and volcanic action. Thus the life of man was found to be intimately connected with the volcanic activity of the earth.

The compounds formed by plants out of the organic elements, were next examined, and divided into the following groups:—

1. Substances containing principally carbon and hydrogen, including oils and fats.

2. Substances containing carbon with oxygen and hydrogen, in proportions to form water. Sugar, starch, and acids were given as examples.

3. Substances containing the four organic elements, of which albumen, fibrin, and caseine, are the best examples.

The second lecture was given on the 24th of April.

The following classification of foods was presented as the basis of subsequent remarks on the agency of plants in the life of man.

#### CLASS I.—*Alimentary or Necessary.*

##### Group 1. AQUEOUS.—

- a) Pure water.
- b) Liquid food, as soups, tea, beer, &c.
- c) Water in solid food.

##### Group 2. MINERAL.—

- a) From inorganic sources, common salt.
- b) From organic sources, the salts of animal and vegetable tissues.

##### Group 3. CARBONACEOUS.—

- a) Amylaceous, starch in vegetable food.
- b) Saccharine, sugar in vegetable and animal food.
- c) Oleaginous, 1. oils and fats from animals.  
2. oils and fats from plants.

##### Group 4. NITROGENOUS.—

1. Vegetable, albumen, fibrin, and caseine.
2. Animal, albumen, fibrin, caseine, and gelatine.

#### CLASS II.—*Medicinal or Auxiliary.*

##### Group 1. ALCOHOLIC.—Wines, spirits, beer.

##### Group 2. ACIDS.—Oxalic, citric, malic, tartaric.

##### Group 3. VOLATILE OILS.—Pepper, mustard, cinnamon, cloves.

##### Group 4. NEUTRAL PRINCIPLES.—Theine, caffeine, theobromine.

##### Group 5. NARCOTICS.—Opium, hemp, tobacco.

The lecturer stated that this classification was necessarily very imperfect, but it would serve as a method. Beginning with the aqueous group, he called attention to the fact of the large quantity of water contained in our ordinary food. Thus:—

Milk	contained	78 per cent.
Butchers' meat	"	63 "
Fish	"	79 "
Potatoes	"	75 "
Turnips	"	87 "
Bread	"	46 "
Flour	"	14 "
Barley	"	14 "
Rice	"	13 "

Where, however, articles of food contained little water, it was necessary to take it either alone or in the form of various beverages.

1. Water is necessary in diet as forming part of the tissues of the human body. A man weighing 154 pounds has 120 pounds of water organized by 34 pounds of solid matter.

2. In dissolving the organic and inorganic constituents of the food, the oleaginous and proteinaceous foods, as well as sugar and the salts, must be dissolved before they can get into the blood.

The mineral group of substances was next examined. Although it was possible that these might be supplied by the drinking of impure water, this practice was denounced as dangerous, and the salts of the animal and vegetable tissues used as food were regarded as the sources of these materials. Ashes obtained from the incineration of various plants used

as articles of diet, were exhibited, as from water-cresses, potatoes, apples, flour, cheese, and others. The danger of depriving the system of the mineral elements of food by cooking, was pointed out, and the benefit derived from eating uncooked foods, as salads and fruits, in certain forms of disease, referred to. Attention was drawn to the following table as containing the quantities of inorganic or mineral matters in certain common articles of diet. In 100 parts:—

Wheat	contains . . . .	1.6
Barley	" . . . .	3.5
Rye	" . . . .	1.7
Rice	" . . . .	0.5
Oats	" . . . .	3.0
Potatoes	" . . . .	0.9
Maize	" . . . .	1.0
Coffee	" . . . .	7.0
Cheese	" . . . .	5.0
Milk	" . . . .	0.6
Butchers' meat	" . . . .	0.5
Fish	" . . . .	1.0

Of the thirty-four pounds of solid matter found in a human body weighing 154 lbs., twelve of them had been computed to be mineral. A large proportion of this was phosphate of lime in the bones, but as this was removed, and needed renewal, it was of great consequence that food containing it and the other mineral substances should be constantly supplied. The elementary constitution of the mineral food was next examined. The first element spoken of was sulphur. This substance was not only present in the inorganic compounds as an element in sulphates, but it was frequently found in combination with protein, as in albumen and fibrin. Sulphate of lime was found in the pancreatic juice, and sulphates occurred in the secretions, as the result of the decomposition and oxidation of the proteinaceous tissues of the body.

Phosphorus and its compounds were next examined. Like sulphur, it presented itself with the protein compounds, but its more important combination was that of phosphate of lime, which entered so largely into the composition of the bones of all the higher vertebrate animals and man. The great source of this substance to man, and the animals on which he fed, were the *Graminaceae*, a family of plants which would only grow when supplied with phosphates. The history of the supply of phosphates as manures for the cereal crops in the artificial agriculture of Europe, was then gone into, and the relation between these mineral elements and the life of man pointed out.

## NORTH LONDON MEDICAL SOCIETY.

APRIL 14, 1858.

MR. ERICHSEN, President, in the Chair.

The PRESIDENT made a communication on

### DISEASE OF THE SACRO-ILIAC SYNCHONDROSIS.

He stated that in the observations he was about to make he intended to depart from the usual custom of the Society, that of "reading a paper." His communication would be oral, not written. Medical Societies were of two kinds, the purely scientific, which published transactions, and those which partook of a mixed character, being social as well as scientific, having for their object the bringing together of Practitioners practising in the same neighbourhood, and thus establishing a good and friendly feeling in the Profession. Now, in the purely scientific Medical Societies it was desirable that the communication made should be in writing in order to secure that accuracy which was necessary for purposes of publication, and to avoid the possibility of after disputes, as to opinions advanced. But in local societies, such as this, he thought that written communications might very advantageously be dispensed with in many instances, and oral ones substituted. He believed that the labour of "writing out" a paper deterred many, as it had often done him, from bringing forward communications, and that members listened with more interest and attention to what was spoken than to what was read. He, therefore, would make the following commu-

nication orally, and hoped that that example would be followed, as he felt sure it would be advantageous to the Society.

#### SACRO-ILIAC DISEASE.

MR. ERICHSEN remarked that this disease had received less attention from writers on surgery than its importance deserved. It was of especial importance in reference to those forms of hip disease, which commenced in the pelvic bones, and which had acquired special interest of late in consequence of being subjected successfully in many cases to operative interference. The disease in question appeared to be of a strumous character. It affected chiefly young adults between the ages of 18 and 30. He had not noticed it in children. The nature of its occurrence in young adults might possibly be that the sacro-iliac articulation undergoes a change as the subject approaches adult life. In infancy a synovial membrane is found there, which, according to anatomical writers, disappears when the period of puberty is reached. The symptoms that characterised this disease are, pain of a dull, aching character, about the hip and gluteal region, increased on pressure along the line of articulation; the occurrence of an indolent swelling, which slowly suppurates; a degree of lameness as characterised by stiffness of gait and inability to stand on the affected limb; lengthening of the limb on the affected side in consequence of the side of the pelvis being pushed forwards; and lastly, abscess in several situations in the gluteal or lumbar regions. The prognosis in these cases was unfavourable, the patients generally eventually dying of hectic. The diagnosis was important; it had to be made from hysterical affections of the hip, from sciatica, from coxalgia, and from spinal disease. The author entered minutely into these points of diagnosis. As to the treatment, rest, counter-irritation, and anti-strumous measures, constituted the chief means to be employed. In connexion with this subject, Mr. Erichsen mentioned the particulars of two cases in which he had recently resected the upper end of the femur, laid bare considerable portions of diseased pelvic bones, in one case removing the tuber ischii, the ascending ramus of the ischium, the acetabulum, and a portion of the ilium, the patient doing well.

MR. PART proposed, and Dr. SHARPEY seconded, a vote of thanks to the author, and a discussion followed, in which Mr. Part, Mr. Lord, Dr. Sharpey, Mr. Jackson, and Dr. Hare, took part.

#### MEDICAL NEWS.

**ROYAL COLLEGE OF SURGEONS.**—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at the meeting of the Court of Examiners on the 7th inst. :—

CODRINGTON, OLIVER, Castle-street, Falcon-square.  
COOKE, GEORGE P., Her Majesty's Dockyard, Woolwich.  
DALTON, HENRY AUGUSTUS, Royal Navy.  
DANIEL, RICHARD SYLVESTER, Manchester.  
DRYSDALE, CHARLES ROBERT, London.  
HALL, EGBERTON FRANCIS, Middleton Cheney, Banbury.  
HEELAS, NEWTON, Wokingham, Berkshire.  
HUDSON, ARTHUR CORT, Manchester.  
LEWER, ALFRED, Merley-hall, Wimborne, Dorset.  
SEWELL, WILLIAM MALLETT, Barnsbury-park, Islington.  
THOMAS, ROBERT GRIFFITH, Swansea, South Wales.

Also on May 10,

DEVLIN, HENRY WILLIAM, Greenhill, Ballygawley, county Tyrone.  
EARLE, JAMES NEALE, Brunswick-street, Trinity-square.  
FAWKNER, JOHN, Manchester.  
GRIFFITH, THOMAS, Warrington, Lancashire.  
HOLLINGS, ROBERT, Woodlesford, near Leeds.  
JACKSON, JOHN, Leicester.  
ORD, GEORGE RICE, Brixton-hill.  
SPENCER, HENRY BANKS, Chippenham, Wilts.  
TOWNSEND, EDWARD RICHARD, Cork.  
WAIT, JOHN STUBBS, Bury, Lancashire.  
WALKER, HENRY, Malton, Yorkshire.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, May 6, 1858 :—

BAYLEY, JOSEPH, Odiham, Hants.  
BEDFORD, ROBERT JAMES, Sleaford, Lincoln.  
BOND, FLORENCE ST. QUINTIN, Brighton.  
EATON, FREEMAN JAMES, Kimpton, Leicestershire.  
HARRIES, JOHN DAVIES, Shrewsbury.  
JEPSON, OCTAVIUS, Gainsborough.  
SLATER, ROBERT, Denton, near Manchester.  
STOCKER, EDWARD CLEMENT, Congleton, Cheshire.

**UNIVERSITY OF ST. ANDREW'S.**—List of Gentlemen on whom the Degree of Doctor of Medicine was conferred, May 7, 1858 :—

BARBOR, THOMAS, M.R.C.S.I., Dublin.  
BRALE, GEORGE B., M.R.C.S. and L.A.C., London.  
BECKETT, CHARLES, M.R.C.S., Hull.  
BOWEN, E., M.R.C.S. and L.A.C., Late Royal Artillery.  
BREMNER, GEORGE, M.R.C.S. Ed., Huntley.  
BRENNAN, THOMAS W., M.R.C.S.I., Dublin.  
CHAPLIN, THOMAS, M.R.C.S. and L.A.C., London.  
COOK, HENRY, M.R.C.S., H.E.I.C.S.  
DOUGLAS, ALLEN E., M.R.C.S.I., Kingstown.  
DOWN, G., M.R.C.S. and L.A.C., Kennington, London.  
GRIFFIN, R. W. W., M.R.C.S. and L.A.C., Weymouth.  
HARRIES, GEORGE J., M.R.C.S., Bath.  
HARRISON, J., M.R.C.S. and L.A.C., London.  
HILSTON, DUNCAN, M.R.C.S. Ed., Glasgow.  
HOGE, F. R., M.R.C.S., and L.A.C., London.  
INCE, EUGENE S., M.R.C.S. and L.A.C., London.  
KNAGGS, HENRY G., M.R.C.S. and L.A.C., London.  
LAING, JOHN, M.R.C.S. Ed., Aberdeenshire.  
MACKENZIE, JOHN, M.R.C.S. Ed., Fort Augustus.  
O'NEILL, EDWARD, J., M.R.C.S.I., Dublin.  
PALFREY, JAMES, London.  
PALK, HENRY, M.R.C.S., Southampton.  
POTTER, HENRY, M.R.C.S.I., Limerick.  
PRICE, WILLIAM P., M.R.C.S., Margate.  
RULE, SAMUEL, M.R.C.S., Plymouth.  
SHETTLER, R. C., M.R.C.S. and L.A.C., Rumbold, Dorset.  
SPACKMAN, W., M.R.C.S. and L.A.C., Lutterworth.  
THOMSON, ALEXANDER, M.R.C.S., Ed., Dublin.  
WAYLEN, A. R., M.R.C.S. and L.A.C., Australia.  
WILLIAMS, J., M.R.C.S. and L.A.C., Wrexham.  
WOOD, ALFRED J., F.R.C.S., Gloucester.

#### DEATHS.

DINHAM.—April 30, at Stratton, Cornwall, John Dinham, L.S.A. 1838; M.R.C.S. Eng. 1839, aged 45.

EDWARDS.—May 5, at Howley-place, Maida-hill, Dr. Edgumbe Windeatt Edwards, late Physician-General, Bombay Army.

FOWLER.—Mr. Charles Fowler, of Cheltenham, died at Weston-super-Mare on the 4th inst., aged 61, sincerely regretted by all who knew him. Mr. Fowler was born at Uckington, in 1797, his father, the Rev. H. B. Fowler, Vicar of Elmstone Hardwick, being at the time also Head Master of the Cheltenham Grammar School. He received his early education at Christ's Hospital, and, being intended for the Medical Profession, was articled to his brother, then practising as a Surgeon in Cheltenham. He subsequently pursued his studies at St. Bartholomew's Hospital, at Edinburgh, and Paris; and, having passed the Royal College of Surgeons in 1822, shortly after entered upon that professional career as a Surgeon and General Practitioner which, earnestly and zealously adopted and persevered in, in due course acquired for him an extensive practice, and afforded a field for the exercise of that skill

as an operative surgeon and of those abilities which ultimately obtained for him a rank in his Profession to which it is the good fortune of comparatively few provincial practitioners to attain. He was elected an Honorary Fellow of the Royal College of Surgeons when that Institution obtained its new charter. His services through life were as generously rendered to the suffering and the afflicted in the humblest walks of life, as in the wealthier circles of society. He obtained, in 1825, the honorary appointment of Surgeon to the Cheltenham General Hospital and Dispensary, an appointment which he held for nearly thirty years, only resigning it when the claims of his extensive private practice, and, still more, the premonitory symptoms of declining health, compelled him to retire from this arduous and honourable office. The *Cheltenham Looker-On* says:—"How much Cheltenham is indebted to the late Mr. Fowler for his zealous and disinterested exertions in behalf of this institution, will never be fully known; but those who were personally intimate with him will bear cheerful testimony to the fact that but for those exertions, the noble and appropriate building we now see in the Sandford-road, would, in all human probability, never have been called into existence. In a philanthropic sense, therefore, the deceased may be considered to have been essentially a public man, and the public was not slow to recognise its obligations to him; for, in 1856, when Mr. Fowler's physical system experienced that severe shock which incapacitated him from further professional labour, and his private friends and patients proposed to present him with some substantial evidence of the respect they entertained for his personal character, many parties came forward as contributors to the fund whose knowledge of that character was derived solely from his public acts, not being themselves either personally or professionally acquainted with him. Probably a more spontaneous expression of feeling was never rendered than that which, upon this occasion, marked the close of Mr. Fowler's professional career—between sixteen and seventeen hundred pounds being subscribed in the course of a very few weeks, wherewith to purchase a suitable testimonial to the value and efficiency of his eminent public services, and of the regard entertained for him in the various relations of private life. Of this large sum £1600 was invested in Bank Stock, settled upon Mrs. Fowler and her two children; the balance being expended in the purchase of a very handsome casket, surmounted by a model, in silver, of a beautiful group of marble statuary, representing the 'Good Samaritan,' presented by Mr. Fowler and his friends to the Cheltenham Hospital, the vestibule of which it most appropriately adorns."

**FURSE.**—April 30, at Southmolton, Devon, Robert Furse, jun. aged 22.

**HERDSON.**—January 28, on board the Omer Pasha, Robert Herdson, Grange, Edinburgh, aged 23 years.

**LANGMORE.**—May 5, at 40, Finsbury-square, William Langmore, M.D. M.A. Edin. and Glasgow, 1809; M.R.C.S. Eng. 1806; L.R.C.P.; aged 74.

**THORBURN.**—April 29, at Liverpool, William Thorburn, M.D. St. And.; and L.R.C.S. Edin. 1844.

**APPOINTMENTS AT VAL-DE-GRAVE.**—M. Perrin has been appointed by concours as *agregé* or assistant professor at the Military Hospital, Val-de-Grâce, having to fill the chair of operative surgery, left vacant by the nomination of M. Legouest to the Professorship.

**PRIZE QUESTION.**—M. Ferrus has offered a prize for the best essay on the following question:—"A comparative examination of cretinism, imbecility, and idiocy under the threefold point of view of their etiology, symptomatology, and pathological anatomy." The essay to be forwarded to the Secretary of the "Société Médico-Psychologique," or to M. Masson, the Medical Publisher, Place de l'Ecole de Médecine, before January 19, 1859.

**SWALLOWING ARTIFICIAL TEETH.**—Scarcely a month passes in which we do not hear of some one swallowing artificial teeth, and that serious consequences have not more frequently resulted from it, is really wonderful. A Medical

gentleman of Baltimore called on the senior editor a short time ago, in a state of great alarm from having swallowed, an hour or two before, a gold plate, extending from the first molar on one side to the second bicuspid of the superior maxillary on the other, with three artificial teeth, two bicuspid a lateral incisor, and a clasp at each extremity. His first impulse after the occurrence of the accident, was to call on one of his Medical friends, who regarding the case as one of dentistry, and as not coming strictly within his province, advised him to consult the senior editor. Although the teeth and plate were now beyond the reach of the dentist, he nevertheless expressed the belief that inasmuch as they had made their way through the oesophagus into the stomach without much difficulty, they would traverse the remaining portion of the alimentary canal, and escape from the anus without injury, which they did in seventy-two hours from the time they were swallowed. A similar accident occurred in Cincinnati, Ohio, about four years ago, and more recently, another in London. We have also heard of several other accidents of the same kind, and it is stated in a late number of the Boston Traveller, that Mr. Bartlett, of Swampscott, Mass., swallowed while asleep a gold plate with six artificial teeth attached, which lodging in the upper part of the oesophagus, came very near causing his death, but fortunately he was relieved the next day, by the removal of the piece by Dr. Pearson of Salem. The only fatal result from an accident of this kind of which we recollect to have ever heard, occurred some months ago at the Bellevue Hospital, in New York. The subject, Mr. McDougall, having swallowed a gold plate with two artificial teeth attached, they lodged in the oesophagus about two inches above the cardiac orifice of the stomach, as was, after his death, ascertained by post-mortem examination of the body. They produced ulceration at the point where they had lodged, which extended through into the pericardium, and ultimately caused the death of the patient. Dentists applying artificial teeth which are not securely attached by clasps to remaining natural teeth, should impress upon their patients the importance of removing them from the mouth at night before going to bed, indeed this should always be done.—*American Journal of Dental Science.*

**CIVIL CONTINGENCIES.**—Under this head of government expenditure in 1857, appears the sum of £351 16s. 2d. to Professor Taylor for his services in the analysis and examination of bodies, and of £1165 to Drs. Thompson, Odling, and Sandison for helping to enforce the provisions of the Smoke Nuisance Abatement Act, of 1853.

**WIND OF A SHOT.**—The following extract from an Indian letter confirms the doubts entertained as to deaths attributed to the "wind of a shot":—"Brigadier Russell is also about to leave the army, under the advice of a Medical Board. Never, perhaps, in all the chances of war has there been such an escape as his. A cannon ball cut the gold watch-chain at the back of his neck as cleanly as if it had been a pair of nippers, and did him no further injury, except inflicting a shock to his nervous system."

**THE VACANT CHYMISTRY CHAIR AT EDINBURGH.**—Several candidates are in the field for the chair of Chymistry in Edinburgh University, rendered vacant by the death of Professor William Gregory; among whom are Dr. George Wilson, Regius Professor of Technology in that University, and Dr. Thomas Anderson, Professor of Chymistry in Glasgow University.

**THE GERMAN HOSPITAL.**—A ball, under the auspices of Her Royal Highness the Duchess of Cambridge, and Her Royal Highness the Princess Mary of Cambridge, took place at St. James's-hall, on Friday week. This hospital, which is situated at Dalston, was opened for the reception and cure of natives of Germany, and others speaking the German language, in October, 1845, and has been found to answer the most sanguine expectations of its promoters. Among the foreigners living in London it is estimated that no less than six-sevenths, or upwards of 30,000, are natives of Germany, or of German provinces subject to other States. It is supported entirely by voluntary contribution, and the receipts during the year 1856 were £3617 5s. 7d., while the expenditure during that period, exclusive of repairs, scarcely exceeded £2850. The number of in-patients was 919, and that of the out-patients who obtained relief at the hospital and the two dispensaries, was 9323, besides 770 dental cases.

**COMMISSIONER YEH ON ANATOMICAL STUDIES.**—The following is from a very interesting portrait of Yeh by the *Times*' China Correspondent:—"He is fond, also, of exhibiting his stock of quack medicines to Mr. Cotton, the ship's Surgeon. Report says, although we have been unable to get Yeh to tell us this, that the Viceroy's father was an apothecary. The son manifests great interest in European surgery. The most liberal admission I ever heard him make was upon this subject. Mr. Cotton asked him whether the Chinese surgeons study anatomy. He answered, 'No; it would be impolitic to do so in China.' Mr. Cotton replied that in former times it was so with our people. Their objection to dissection was so great, that Surgeons were obliged to study by stealth; but now people were so alarmed at having to be attended by Surgeons who had not studied the human body, that the practice is rendered legal. Yeh answered, that he could only say the people would not endure such a thing in China. 'But do you think it objectionable?' 'My individual opinion is, that dissection for knowledge sake is not wrong.'"

**DELIRIUM TREMENS IN THE GUARDS.**—A correspondent, referring to a late Parliamentary return on the subject of mortality in the Guards, denies that *delirium tremens* is a common disease among the privates of these regiments. He quotes from a report by Sir A. Tulloch and Dr. Balfour the following passage:—"Brain fever of drunkards, which is almost invariably the direct result of intemperance, prevails to a much less extent among the Foot Guards than in the cavalry or infantry of the line; the ratio of admissions by it has been among the Dragoon Guards and Dragoons 0.94, and of deaths 0.13; among the infantry 0.74, and of deaths 0.13; among the Foot Guards 0.16, and no deaths. We are not disposed to attribute this difference to the habits of the Guards being more temperate, but rather to the circumstance that while the troops of the Line, particularly in Scotland and Ireland, indulge freely in the use of ardent spirits, the common drink of the Guards, as of the lower orders in London, consists of beer, which has comparatively little tendency to induce *delirium tremens*, even when indulged in to a considerable extent."

**UNIVERSITY OF LONDON.**—On Wednesday week, the presentation of degrees took place, after an address from the Chancellor, Earl Granville. The hall at Burlington House was crowded, and there were many ladies in the assembly. The order for presentation for degrees was as follows, omitting those in Arts and Laws:—University College—Edwyn Andrew, M.D.; James Gibbs Blake, M.D.; John Footman, M.D.; Henry Maudsley, M.D.; John Dewherst Scurrah, M.D.; John Charles Thorowgood, M.D.; Julius Woldemar von Tunzelmann, M.D. King's College—David Conway Evans, M.D.; Henry Stevens, M.D. Guy's Hospital—Thomas Edwin Burton Brown, M.D. St. Thomas's Hospital—Edward Clapton, M.D. Jervis-street and Middlesex Hospitals—William Burke Ryan, M.D. Queen's University in Ireland—Thomas Dunbar Ingram, LL.B. University College—Alfred Bingham, LL.B.; George Knott, LL.B.; Henry Carne Oats, LL.B.; James Stevens, LL.B. Owens and University Colleges—William Dinwiddie, LL.B. University of Edinburgh—Thomas James Walker, M.B. University College—Michael Castaneda, M.B.; St. John Edwards, M.B.; James Fawcus, M.B.; William Tilbury Fox, M.B.; William Price Jones, M.B.; John Zachariah Laurence, M.B.; Walter Bassett Ramsbotham, M.B.; Henry Montague Duncan Smith, M.B. King's College—Francis Edmund Anstie, M.B.; Thomas Buzzard, M.B.; Charles James Devonshire, M.B.; Henry Stavely Thaddeus King, M.B.; George William Lawrence, M.B.; Alfred Meadows, M.B.; Augustus Pout, M.B.; John Lumsden Propert, M.B.; John Way, M.B.; Antony Whitford, M.B. St. Thomas's Hospital—William Miller Ord, M.B. Middlesex Hospital—Arthur John Cribb, M.B. St. Bartholomew's Hospital—John Lempiere De la Garde, M.B.; Michael Thomas Sadler, M.B.; William Turner, M.B. Westminster Hospital—Frederick William Wilson, M.B. Guy's Hospital—Uriah Perrin Brodribb, M.B.; Samuel Giles, M.B.; Frederick Moon, M.B. Queen's College, Birmingham—Francis Thomas Bond, M.B. Hull and E. Riding School—Henry Carnley, M.B. Trinity College, Cambridge—Edward Ernest Bowen, B.A. Trinity College, Dublin—Newton Price, B.A. The graduates having been severally presented to the Chancellor, the presentation of scholars, exhibitioners, medalists, and prizemen, then took place. The

names of all candidates who obtained honours in the course of the past year were read; but those gentlemen only who obtained scholarships, exhibitions, medals, or prizes, were presented to the Chancellor, in the following order:—Thomas James Walker, M.B. University of Edinburgh, scholarship and medal in physiology and comparative anatomy; Thomas Buzzard, M.B. King's College, scholarship and medal in surgery; William Tilbury Fox, M.B. University College, scholarship and medal in medicine; Francis Thomas Bond, M.B. Queen's College, Birmingham, medal in physiology and comparative anatomy; William Miller Ord, M.B. St. Thomas's Hospital, medal in surgery; George William Lawrence, M.B. King's College, medal in medicine; William Miller Ord, M.B. St. Thomas's Hospital, medal in midwifery. *First Examination.*—Felix Henry Kempster, M.B. University College, exhibition and medal in anatomy and physiology; Walter Moxon, M.B. Guy's Hospital, exhibition and medal in materia medica; Felix Henry Kempster, M.B. University College, exhibition and medal in Chemistry; William Miller Crowfoot, M.B. St. Bartholomew's Hospital, medal in anatomy and physiology; Walter Moxon, M.B. Guy's Hospital, medal in chemistry; Walter Rivington, M.B. London Hospital, medal in materia medica; Samuel Hoppos Adams, M.B. University College, medal in botany. *Matriculation.*—Frederick Brown, Trinity College, Cambridge, exhibition in mathematics; Edward Nicholson, St. Mary's Hospital, prize in chemistry; Charles Hilton Fagge, Guy's Hospital, prize in botany; Henry Charlton Bastian, self-tuition, prize in zoology.

**CHOLERA IN ST. PETERSBURG.**—The total number of cases that have occurred in this city from the commencement of the epidemic in October 1852 to the end of January 1858, amounts to 31,689; of these 17,174 have recovered, 14,507 have died, and 8 remain under treatment.

**REVACCINATION OF THE PRUSSIAN ARMY IN 1857.**—In the report for 1857 it is stated that there were during that year 45,521 soldiers vaccinated or revaccinated. The marks of prior vaccination were plain in 38,381, not plain in 4834, did not exist in 2306,—45,521. The vaccinations performed in 1857 pursued a regular course in 28,937, pursued an irregular course in 5627, were without effect in 10,957,—45,521. The unsuccessful cases were vaccinated again, with success in 3117, without success in 7840,—10,957. Hence it follows that there were 63 per cent. successful vaccinations, or including those vaccinated a second time with success, more than 70 per cent., a proportion agreeing with that observed during 1856. Among the soldiers who had been successfully revaccinated during 1857 or earlier years, there occurred during 1857, 4 cases of varicella, 2 of varioloid, and 1 of true variola, this last being very slight. Throughout the entire Prussian army there occurred only 35 cases, viz. 10 of varicella, 20 of varioloid, and 5 of variola. The majority of these cases—21, occurred in recruits not yet revaccinated, 7 occurred in subjects revaccinated without success, and 5, as already mentioned, in soldiers successfully revaccinated. And although variola prevailed in many places epidemically among civilians, yet we find in this large army so protected, only 35 cases of all the varieties occurred, of which only 5 were examples of true small-pox, and only 1 soldier died thereof!

**LIST OF Scholarships and Prizes awarded to the Medical Students of King's College, London, at the meeting held in the great hall of the College, on Saturday, May 8,—the Lord Bishop of London in the chair.**—**SCHOLARSHIPS.**—John Harley, Senior Scholar, George James Symes Saunders, Second Year Scholar; James Usher Huxley, George Fortescue, Charles Henry Allfrey, Junior Scholars; John Barr Brown, John Amos Woodhams, John Frederick Cobb, Warneford Scholars, First Class; Frederick Fawcett, Warneford Scholar, Second Class. **PRIZES AND CERTIFICATES OF HONOUR.**—*Winter Session, 1857-8.*—*Divinity:*—Robert Batho, Robert Charles Brown, second year; Charles Henry Allfrey, first year; *Prizes.* Warneford Endowment:—Edmund Symes Thompson, First Prize; Richard Whitfield Hewlett, Richard Hughes, Second Prize. Leathes' Endowment:—Edward Sharp, First Prize; Edmund Symes Thompson, Second Prize. Gill Prize:—Decimus Curme. *Anatomy:*—Edward Sharp, Prize; William Davies, John Sealy, George Moule Evans, second and third years; John Barr Brown, Augustus Robinson Hall, William Edger, first year; *Certificates of Honour.* Physiology:—

Robert Batho, Prize; Edward Sharp, James Beale Horton, second and third years; Augustus Robinson Hall, William Batho, first year; Certificates of Honour. Chemistry:—Robert Charles Brown, Prize; Edward Sharp, second year; William Edger, John Barr Brown, first year; Certificates of Honour. Medicine:—William Cayley, Prize; John Easton, Thomas Shadford Walker, Arthur Julius Pollock, Robert Batho, Edmund Symes Thompson, Certificates of Honour. Surgery:—James Beale Horton, Edmund Symes Thompson, Esq.; Thomas Cayser, Frederick Fawcett, Esq.; Walter Fry; Certificates of Honour. Dr. Todd's Clinical Prizes:—John Harley, First Prize; Arthur Ernest Sansom, Second Prize. Clinical Surgery:—Edmund Symes Thompson, Prize; John Harley, Frederick Fawcett, Walter Fry, Certificates of Honour. Clinical Medicine:—Thomas Shadford Walker, Prize; William Cayley, Edmund Symes Thompson, Esq., Certificates of Honour. Medical Society:—Arthur Ernest Sansom, Prize. Summer Session, 1857.—Practical Chemistry:—John Easton, Prize; Henry Banks Spencer, John Harley, Certificates of Honour. Forensic Medicine:—Henry Banks Spencer, Prize. Botany:—George James Symes Saunders, Prize; Robert Batho, Frank Pout, Certificates of Honour. Midwifery:—Thomas Cayser, Prize; John Easton, Edmund Symes Thompson, Frank Pout, Certificates of Honour. Materia Medica:—Robert Charles Brown, Prize; George James Symes Saunders, Reginald Croft Lever, Thomas Bowerman Belgrave, Certificates of Honour. Comparative Anatomy:—James Wyard Gooch, Prize; Charles Parsons, Edward Harris, Certificates of Honour. Clinical Medicine:—John Walters, Prize; John Henry Hartley, Certificate of Honour. Clinical Surgery:—William Liddon, Prize. NAMES OF THOSE ELECTED ASSOCIATES OF KING'S COLLEGE, LONDON.—John Alcock, Alfred Fleischmann, John Harley, James Beale Horton, Francis Mason, Edward Evan Meeres, Charles Bambridge Rendle, Arthur Ernest Sansom, Samuel Spradly, Montague James Sturges, Morris Tonge, John Walters.

REPORT OF THE BELGIAN ACADEMY OF MEDICINE ON VACCINATION.—The following are the conclusions of an elaborate report made to the Academy by a Committee consisting of M.M. Craninx, Verheyen, and Marinus:—1. The preservative power of vaccine virus is absolute in almost the totality of cases. 2. In a very small number of cases in which the virus has only imperfectly destroyed the constitutional predisposition to variola (which cannot be ascertained by any appreciable sign), this preservation lasts only for a time, the duration of which cannot be assigned, but which does not cease prior to the seventh, or even the tenth year after vaccination. 3. The cases of variola supervening on vaccination are few in number, and in general are very slight, consisting in most cases in an eruption called from its mildness *varioloïd*. 4. Variola may appear after variola, as well as after vaccination. 5. Human vaccine virus becomes gradually weakened by successive transmissions, without, however, entirely losing its preservative property. It is, therefore, both useful and necessary to renew the lymph whenever true cow-pox matter can be procured. 6. The regenerated virus produces a finer eruption, the course of which is slower and more regular than that of the old virus. 7. The reaction or vaccinal fever which accompanies the eruption is more marked and active—a condition of its preservative power. 8. The number of pustules produced by this lymph is greater, and they appear on individuals who had resisted the influence of the old virus. 9. The new lymph succeeds better in revaccinations than the old. 10. The lymph should be taken from the finest and the best-developed pustules. 11. Primary vaccine lymph exists in Belgium as well as in other countries. 12. To obtain a due supply of cow-pox, the Government should accord premiums to the proprietors of cows who promptly make known the existence of true cow-pox. 13. Rewards should also be decreed to medical and veterinary practitioners, who by their zeal contribute to its discovery and propagation. 14. Revaccination is the useful and indispensable complement of a first vaccination, not that it is always necessary, but in order that certainty may be acquired that all disposition to the receptivity of variola has been extinguished in the economy. 15. From the tenth to the fifteenth year is the best time for a revaccination, supposing the subject to have been vaccinated in early infancy. 16. If the revaccination succeeds, we have a right to believe in the continuance of the preservation against variola. If it fails it should be repeated at more or less distant intervals, so that

we may be assured by these test-vaccinations of the immunity of the subject. 17. Vaccination, far from having had an injurious influence upon mankind, has delivered it from the scourge of small-pox, and the various evils and infirmities which accompany or follow this. It is an error to charge it with having led to the physical and moral degeneracy of mankind. 18. Vaccination and revaccination cannot be rendered compulsory in Belgium, but it is incumbent upon the Government, having as its duty to watch over all that concerns public health, to employ all means at its disposal in order to extend and generalize the practice. Then follow various recommendations to this end.

## VITAL STATISTICS OF LONDON.

Week ending Saturday, May 8, 1858.

### BIRTHS.

Births of Boys, 868; Girls, 820; Total, 1688.  
Average of 10 corresponding weeks, 1848-57, 1629.

### DEATHS.

	Males.	Females	Total.
Deaths during the week ...	550	506	1056
Average of the ten years 1848-57 ...	530.6	518.8	1055.4
Average corrected to increased population ...	...	...	1161
Deaths of people above 90 ...	...	...	6
Deaths in 15 General Hospitals ...	33	16	49

### DEATHS IN SUB-DISTRICTS FROM EPIDEMICS.

	Population. 1851.	Small-pox.	Measles.	Scarlatina.	Whooping-Cough.	Diphtheria.	Typhus.
West ....	376,437	2	8	6	8	1	3
North ....	490,396	..	9	3	14	1	6
Central ..	893,266	..	2	9	18	2	5

Whole amount of rain in the week ...	...	...	0.21 in.
Amount of horizontal movement of air in the week ...	...	...	355 miles.

## TO CORRESPONDENTS.

Dr. Heslop's paper, on "Diphtheria and its Treatment," is in type, and will appear next week.

Sir Philip Crampton.—The last bulletin was, "A quiet night, but very weak."

Dr. Budd's paper, on "Diabetes," arrived too late for this week's number.

M.D.—The following are the formulae alluded to in Dr. Symond's lecture last week:—

℞ Quin. sulph. ℥j. to 3ss. pil. galb. co. ℥ij. ext. Conii ℥j., ℥i. divide in pil. xx., cap. ii., bis terve die.  
℞ Zinc, ox. ℥j., ext. valer., ℥ij., hyos. ℥j., ℥i. div. in pil. xx., capt. ij., ter die.

Mr. Lloyd.—A paper, on "Displacement of the Ovary," by Dr. Rigby, will be found in our first volume for 1856, page 6.

Chirurgicus.—The salary of the Inspector of Anatomy is limited by Act of Parliament to £100 a-year.

Quæst.—The Rev. Doctor is of Cambridge University, not the University of Cambridge.

F.R.S.—We never heard of any Medical man introducing his female relatives to a speculum *à l'usage*.

Philothetes.—The pretended quotation is an impudent forgery. If our correspondent could suggest any plan of punishing the quacks who advertise their filthy works with pretended notices of approval by the Medical Journals, we should be only too glad to submit it to our Solicitor.

**Obstetricus.**—Some years ago a woman was run over in the Borough by a coach, and killed. She was taken to St. Thomas's Hospital, and a living child removed by the Cæsarean Section.

**A Poor Assistant.**—We know of no way of removing the red stains produced by nitric acid on black cloth. Probably some of the dyes sold as "Revivers" might answer.

The conclusion of Dr. Hamilton Roe's paper is unavoidably delayed until next week.

**Errata.**—In Dr. Symonds' Second Lecture, Page 395, 6th line from bottom, second column, for "constitutional" read "constitution, whether."—Page 396, 13th line from top, 1st column, for "sufficing" read "as."—Page 421, 5th line from top, 1st column, for "a distant organ" read "an organ."—Page 421, 33rd line from top, 1st column, delete "interesting."

Letters by Mr. Hulke, Dr. Morgan, Dr. Silvester, Dr. Whitehead, &c., are in type, but are postponed to a future number.—Letters by Dr. E. Lee, Mr. Field, of Brighton, Dr. Steavenson, of Hastings, on the Encouragement of Homœopathy, and several by gentlemen writing under anonymous signatures on the same subject have been received; but so much space has been devoted to this controversy in recent numbers that we are desirous of restricting the insertion of future communications to the report of resolutions passed at Societies, or by Medical men meeting to discuss the question.

**Horse-Taming.**—The President of the Farmer's Club American Institute, in a recent speech, said:—"In relation to the expense of keeping a horse, I will remark, that I keep my colts till five years old without work, and I can break such a colt in three hours so that he can be mounted, and in three days so that he can be safely harnessed. The secret of breaking a colt is to conquer him, which can be done by fastening up one fore leg, and when he is tired of walking on three legs, throw him by striking out the other fore leg; and when down he gives up, fully conquered. We spoil our colts by early breaking." Mr. W. Ward, writing from 124, Richmond-street, Toronto, Canada West, states that the American horse-taming secret has long been known in that province. Mr. Ward writes:—"I here state Mr. Rarey's theory of taming the horse. Having haltered your colt and caressed him, fasten his near fore foot with a strong strap round the pastern and radius, or fore-arm; fasten his foot up safe; make him hop round on three legs till tired; when he is tired, put a strap, with noose, round the off pastern; make him hop; then pull the strap that is on the off pastern, and he will come on his knees. When on his knees, keep the strap tight, that he cannot get his foot slack to get up. Bear against the horse's shoulder with yours steadily, and he will lie down in a few minutes. When he is down, stroke him the way the hair lies. Take off the straps as soon as he is down. You can now do anything with him you wish."

#### MELBOURNE MEDICAL COLLEGE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Will you have the goodness to inform me through the medium of your Journal, whether there is a Medical College in Melbourne, Australia; if so, what are the facilities for dissecting and obtaining a proper knowledge of the Profession, and whether the Diplomas conferred upon the students will enable them to practise in England. I am, &c.

May 7, 1858.

QUESTOR.

[Perhaps some Correspondent who has been in Melbourne will give a more detailed answer to the above than we can.—Ed.]

#### TYPHUS AND TYPHOID.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I request the favour of the insertion of this note, in order to correct a typographical error in your report of the discussion which followed my paper on Fever, read at the Medico-Chirurgical Society.

Dr. Jenner is made to say,—"Except among Medical men, he had only seen two or three cases of typhoid fever among the better classes."

This remark is directly opposed to what I endeavoured to establish in my paper, viz. that when fever breaks out among those in good circumstances, without any traceable contagion, it is almost invariably typhoid. The truth is, however, that Dr. Jenner said *typhus*, and not *typhoid* fever, was very rare in the better classes of Society. So that his experience is quite in conformity with the view expressed in my paper.

I have Dr. Jenner's authority for writing this note.

I am, &c.

CHARLES MURCHISON, M.D., Assistant-Physician

King's College Hospital, and London Fever Hospital.

31, Sackville-street, W., May 10, 1858.

#### CHLORODYNE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—There was an important error in the formula for making a compound of equal efficacy to Chlorodyne in my last letter, which I did not observe until my attention was drawn to it by your Correspondent, "Surgeon R.N." The formula should have been—dissolve 8 grains of muriate of morphia, and 20 grains of gingerine in an ounce of alcohol and chloroform. The reason why your Correspondent failed to dissolve the muriate of morphia is obvious. Eight grains of that salt are not soluble without the aid of heat in a mixture consisting of half an ounce each of alcohol and chloroform.

I did not promise that my compound was miscible with water. Like Chlorodyne, it can only be suspended in water by means of mucilage, or some such agent.

While writing on this subject I may take the opportunity of giving your readers interested in this Chlorodyne question my formula for preparing that incompressible compound:—Dissolve 8 grains of muriate of morphia in half an ounce of water, and 20 grains of gingerine in an ounce of chloroform. Add to the morphia solution half an ounce of treacle, and 10 drops of essence of peppermint, and mix both solutions together. The result will be a mixture corresponding in its physical and therapeutic properties,

whether disguised by a blue bottle or not, to the compound Chlorodyne, the title of which has been entered at Stationer's Hall, to prevent the piracy thereof; but such entry cannot forbid the employment and manufacture of an imitation under any name with as sweet an odour.

May 8, 1858.

I am, &c.

CHEMIST.

#### COMPULSORY VACCINATION.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The compulsory Vaccination Act is generally admitted to be a failure, and frequently found to be a nuisance. It fails, I think, because its principle is opposed to English notions of liberty, and is a nuisance, because by means of it the unscrupulous parish vaccinator may gain admittance to his neighbour's patient; and because the books and certificates are tedious.

Allow me to propose a method calculated to remove some of these disadvantages, and to induce the poorer classes to come forward more readily.

Let the notice served by the Registrar be somewhat modified, and divisible into two portions; the one to be signed by any qualified practitioner upon his personal inspection of each successful case, on the eighth day, on presenting which to the Registrar, to be endorsed by him and returned, the parent or nurse should receive one shilling. The other portion, properly signed by the same Surgeon, to be presented by him to the Registrar, in exchange for half-a-crown.

Thus we allow the patient to choose his own Surgeon, we allay his fears respecting parish or contract carelessness, compensate the most needy parent for loss of time, and, whilst furnishing to all parties the requisite certificates, avoid the necessity for complicated books.

Also let the time be extended to six months, as it is quite unsafe in winter time, and country districts, to bring from home children so young as three months.

If you will turn these notions adrift upon your columns, to find their own level, you will much oblige an old subscriber.

I am, &c.

JOHN WADHAM ROBINSON.

Mildenhall, Suffolk, May 10th, 1858.

COMMUNICATIONS have been received from—

MR. PAGET; DR. GUY; DR. MARKHAM; DR. CONOLLY; DR. DAY, St. Andrew's; DR. BROWN SEQUARD; MR. LIZARS, Edinburgh; DR. BARKER, New York; MR. H. SMITH; MR. FIELD, Brighton; DR. MURCHISON; DR. LAWRENCE; SECRETARY GENERAL BOARD OF HEALTH; MR. WIELE, Southampton; DR. SILVESTER; DR. CORFE; MR. DON; MR. GRIFFIN; DR. ALTHAUS; DR. STEVENSON, Hastings; DR. MCCORMAC; MR. GRANTHAM, Crayford; DR. CARTWRIGHT, Bradford; JUVENIS; JUSTA AUT NIHI; MR. ROBINSON; MR. CHALMERS; MR. SMART; REGISTRAR GENERAL; MR. HARDY; MR. CATER; MR. WATTS; MR. HAWKES; MR. MARTIN; MR. W. STEVENSON; DR. JEPHSON; MR. SQUIRE; MR. CLARKSON; MR. GREENWOOD; DR. R. ALLDRIDGE; MR. J. BRIDGFORD; MR. METCALFE; MR. BOWLES; MR. TOWNSEND; MR. CAMPBELL; MR. G. WALKER; MR. PLUMRIDGE; DR. BUDD, Bristol; MR. CARRUTHERS.

## APPOINTMENTS FOR THE WEEK.

May 16. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m.; Charing-Cross, 1 p.m.

ROYAL COLLEGE OF SURGEONS, 4 p.m.: Professor Hewett, "On Tumours of the Head;" Professor Busk, "On the Invertebrata;" Professor Quekett, "On the Vertebrata."

ROYAL INSTITUTION, 3 p.m.: Edwin Lankester, M.D., F.R.S., F.L.S., "On the Vegetable Kingdom in its Relations to the Life of Man."

MEDICAL SOCIETY OF LONDON, 8 p.m.

### 17. Monday.

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.; Orthopaedic Hospital, 2 p.m.

### 18. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

ROYAL INSTITUTION, 3 p.m.: J. P. Lacaita, Esq., "On the History of Italy during the Middle Ages."

PATHOLOGICAL SOCIETY, 8 p.m.: (Council, 7 p.m.)

### 19. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Orthopaedic Hospital, 2 p.m.

MICROSCOPICAL SOCIETY, 8 p.m.

PHARMACEUTICAL SOCIETY, 11 a.m.

### 20. Thursday.

Operations at St. George's, 1 p.m.; Middlesex, 1½ p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.

ROYAL SOCIETY, 8½ p.m.

CHEMICAL SOCIETY, 8 p.m.

HARVEIAN SOCIETY, Dr. Charles Crote, "On Infra-mammary Pain."

### 21. Friday.

Operations at the Moorfields Ophthalmic, 10 a.m.; Westminster Ophthalmic, 1½ p.m.; Great Northern, 2 p.m.

ROYAL INSTITUTION, 8½ p.m.: Professor Huxley, F.R.S., "On the Phenomena of Gemination."

## EXPECTED OPERATIONS.

King's College Hospital.—The following operations will take place this day (Saturday), at 2 o'clock:—

Lithotomy; staphylocyst; removal of tumour from lower jaw; removal of warty excrescences from labia; by Mr. Ferguson. For displaced testicle; for varicose veins; amputation of finger; varicocoele. By Mr. Farndale.

St. Mary's Hospital.—The following operation will take place on Wednesday next, at 1 o'clock:—

Vesico-vaginal fistula. By Mr. Brown.

## ORIGINAL LECTURES.

## LECTURES

ON

THE ANATOMY, INJURIES, AND DISEASES  
OF THE HEAD,

DELIVERED IN THE

*Theatre of the Royal College of Surgeons of England.*

By PRESCOTT HEWETT,

Professor of Anatomy and Surgery to the College.

## ON FRACTURES OF THE SKULL.

## LECTURE IV.

At our last meeting, I closed my remarks with a case illustrative of the diagnosis of fracture of the roof of the orbit, of the roof of the nostrils, and of the petrous bone.

There are yet other regions of the base, in which extravasated blood may make its appearance after a severe injury of the base, and thus serve as an indication of the damage done to the bones. Such appearances exist, however, much more rarely than those which we have already noticed, and they certainly do not possess the same value; still they may be of use under certain circumstances.

Extravasation of blood, and consequent discoloration of the skin, appearing in the mastoid region some hours after a severe injury of the head, may lead to the suspicion of a fracture involving the posterior part of the base, and all the more valuable will this sign become, if the injury did not bear directly upon this region, and especially if it bore on the opposite side of the head.

A discoloration of the integuments of the lateral parts of the neck, appearing subsequent to an injury of the head, may also serve as a guide to the diagnosis of a fracture of the base. The blood oozing from the fractured skull gradually infiltrates the cellular tissue of the neck, and thus ultimately reaches the skin which becomes discoloured, as if bruised.

A man, aged 58, was admitted into the Hôpital St. Antoine, with all the signs of an extensive fracture of the base, bleeding from the nose, the mouth, and the right ear, with ecchymosis of the eyelids. Four days after the admission of this patient into the Hospital, the integuments of the right side of the neck became discoloured, as if bruised. The skin becoming ecchymosed thus late, led to the inference that the discoloration was dependent upon a fracture of the base, with oozing of blood through the broken bones into the cellular tissue of the neck, from whence the blood had gradually made its way towards the superficial parts, and ultimately reached the skin. The man died, and the muscles and cellular tissue of the right side of the neck proved to be infiltrated with blood, which had escaped from the inside of the skull, through a fracture at its base.

And so too, may we make good use of a sudden puffiness appearing in the occipital region, with discoloration of the skin, some hours after a severe injury of this part of the head. The large venous sinuses, connected with the occipital, may, when this bone is broken, be torn across, and thus give rise to an extravasation of blood, which, gradually oozing through the line of fracture, may ultimately show itself in the superficial parts, and thus reveal the nature of the injury.

A man, aged 40, was admitted into St. George's Hospital, under the care of Mr. Cesar Hawkins, in February, 1829, with profuse bleeding from the mouth and nose. He was conscious when spoken to; had perfect command of the muscles, but the speech was somewhat indistinct. He had received a heavy blow from a piece of timber falling upon the back part of his head. Two days after his admission he was bled, and apparently with benefit. The following forenoon he suddenly became furiously delirious, and so strong were the convulsions, that he required several persons to hold him down. A considerable swelling now made its appearance at the back of the neck and occipital region. There was no tension, but it was thought advisable to cut down upon the swelling. The occipital was found broken and depressed; but the fragments were so loose, and the spaces between them

so freely open, that the blood escaped readily, and nothing further was done. He sank gradually, and died in the afternoon. The occipital was broken into several pieces. On the right side a fragment, somewhat triangular in shape, was perfectly moveable, and partly depressed. The fracture extended into the foramen magnum, and opposite to this fractured edge was a longitudinal rent in the dura-mater. The upper extremity of this rent just reached the end of the superior longitudinal sinus, from which the principal part of the blood, both internal and external, appeared to have come. Another angle of the fracture ran across the end of the right lateral sinus, whence some of the blood among the muscles of the neck might have proceeded; but it was not observed that the dura-mater was injured at this part. The brain itself was covered with blood, and its substance, as well as that of the cerebellum, was extensively lacerated.

Fractures of the base of the skull, even when clearly recognised, lead but very seldom to operative interference. All our treatment must be directed, not against the broken bones, but against the accompanying symptoms, which will demand all our care, and the strictest antiphlogistic remedies, bearing in mind that we cannot be too vigilant nor too cautious. But I refrain from saying any more on this point at present, as I shall have to bring the subject of the cerebral lesions under your notice in a future lecture.

It may happen, however, that we may be called upon, in some very rare instances, to resort to an operation even in the base of the skull.

A lad, 16 years old, was admitted into St. George's Hospital, under the care of Mr. Cesar Hawkins, in May, 1855, with a compound fracture of the skull. The wound, a lacerated one, and about two inches in length, was immediately over the right brow, and through it was easily felt an extensive and a comminuted fracture of the supra-orbital ridge, with in-driving of some of the fragments, the depression at the upper part being to the extent of half an inch, with a projecting ridge of bone overhanging it. It appeared that half an hour before his admission into the Hospital, this patient had been kicked on the head by a horse, that he had been stunned for about two minutes only, after which he had recovered himself, and spoke intelligibly. The complexion was pale; and the pulse, about seventy, was of natural strength. He answered questions, when sharply spoken to; but, shortly after his admission, became more oppressed in manner, so that it was difficult to get him to speak. This oppression passed off to a great extent after he had vomited freely. At a consultation of the Surgeons, it was determined to operate at once. The fracture was laid bare, and the upper projecting ridge of bone sawn off with Hey's saw; a loose fragment of bone was then removed, and this disclosed a rent in the dura-mater, through which escaped a small portion of brain-substance. Several other smaller fragments were then taken away from the supra-orbital ridge, but there still remained a depressed piece of bone, which appeared to be firmly locked in. After a good deal of trouble, this fragment was displaced, and cautiously drawn out. It proved to be the greater part of the roof of the orbit. The wound was then lightly dressed. It was found advisable to administer a small quantity of chloroform during the progress of the operation. This patient remained perfectly sensible during the day, the only symptom being some occasional twitching of the left arm; and thus he went on for two days, with some slight increase in the circulation, for which he was ordered a mixture with some antimony. On the fourth day, a piece of slough, apparently of brain-substance, made its appearance at the lower part of the wound. On the seventh day, the slough had increased much in size, and, when examined microscopically, proved to be brain-substance. The motions and urine were now passed unconsciously; a few twitches occurred occasionally about the face, and he rambled a good deal. On the following day, he appeared to be sinking; the discharge from the wound was very foul; he was allowed a little meat and porter, and he rallied for a couple of days. On the tenth day, he suddenly became quite blue, with scarcely any pulse, but this soon passed off, to recur again on the following day. A large mass of brain, pulsating very strongly, now protruded through the wound, which was still very foul. And thus he went on for the next three days, when he had another attack of syncope, from which he soon recovered, however, after he had had a little wine. He lingered for four days longer, gradually

getting weaker, with some loss of power about the right arm. During this time the condition of the wound had been improving, and the protrusion of the brain was much less. He died on the eighteenth day after the accident, never having made any complaint as to his knee, and without a symptom to lead to the suspicion that purulent infection had taken place. This is the preparation which was made of the lad's skull. There is a large gap at the anterior part of the base of the skull; in fact, the whole roof of the right orbit, as well as the upper part of the circumference of the orbital arch, is wanting. The preparation is completed by the large fragment of bone, forming the greater part of this roof, which was brought away during the operation, and by several other smaller fragments belonging to the remaining part of this region. The bones of the inner wall of the orbit are also extensively injured; the cribriform plate of the ethmoid, its os planum, and the lachrymal, are all, more or less, broken. In addition to these extensive injuries, there is a lineary fracture starting from the anterior and inferior part of the parietal, and passing obliquely upwards and backwards towards its posterior margin. Extensive suppuration existed between the bone and the scalp, in the neighbourhood of the injury; the dura-mater was torn through, but it was curious to observe how slight were the traces of inflammation in the cavity of the arachnoid. At the part where the brain had protruded through the dura-mater, the visceral and parietal arachnoid were intimately united to each other, and thus the cavity of this membrane was completely closed at this spot. A trace of recently-effused lymph was found at the upper part of the left hemisphere, extending slightly down the longitudinal fissure. The cerebral veins covering the right hemisphere were filled with pus, and pus mixed with blood was found in the longitudinal and in the lateral sinuses. Both lungs were thickly studded with several patches of secondary deposit. All the other viscera were quite healthy, save the spleen, which was large and soft.

Had it not been for the purulent infection which occurred in this case, this lad would certainly have had a chance of recovering. There was but a trace of inflammation about the membranes of the brain, and the cavity of the arachnoid was completely cut off from all external influences by means of the adhesions which had formed. The cerebral symptoms were but slightly marked throughout; the protrusion of the brain had become much less, and the wound itself had put on a healthier aspect; but, unfortunately, there was the deadly mischief of purulent infection, and this it was which killed this patient.

In the case which we have just been considering, a large portion of the anterior fossa of the base was removed during life. The following is a case in which a large portion of the posterior fossa was removed, and that, too, with perfect success. It was a trying case, and one which will ever remain as a beacon, pointing out what may be done in cases even of the most desperate character.

In November, 1808 (a), a midshipman, aged 14, fell from the booms of his ship into the hold, among some provision-casks, a height of about 30 feet, without touching anything in his descent by which his fall might have been broken. At first no marks of external injury were to be found in any part of the body; but there were symptoms of compression of the brain, with a good deal of bleeding from the ears and nose. The head was shaved, and then a puffy tumour was discovered upon the occipital bone. An incision was made into this swelling by the Surgeon of the ship, and thus was laid bare a fracture; but nothing further was done for the moment. The patient was at once removed to the Naval Hospital at Deal, where his ship was lying. Here Dr. Hutchinson carried the incision farther down, cutting through the fibres of the trapezius and complexus muscles. It was then found that the fracture passed perpendicularly down into the foramen magnum, and that there was extensive depression of the bone. Several fragments were detected, one of which was so jammed and depressed under the sound bone, that it was impossible to raise it without resorting to the trephine. A circular piece of bone was therefore cut out between the superior and inferior semicircular ridges. On the removal of the bone, the dura-mater at once protruded, so as to completely fill up, and even extend beyond, the trephine-hole; the membrane itself was quite healthy, but underneath it was some

fluid. The depressed pieces of bone were elevated, and the spicula removed. The brain-symptoms were not relieved by the operation; and, as the state of the parts was pretty much the same on the following morning, it was thought advisable no longer to defer opening the bulging dura-mater, which was still tense, and elastic to the touch. Half an ounce of blood-tinged fluid was thus evacuated, and the dura-mater instantly collapsed. The parts were lightly dressed. The inflammatory symptoms which subsequently supervened were treated by bleeding and purgatives, and under this treatment the patient gradually recovered; but a little oozing of a serous fluid was for some time observed from between the lips of the incision in the dura-mater. At the end of four months after the operation the wound was quite healed, and the patient left the Hospital in good health and spirits.

One other point remains for our consideration in reference to fractures of the base of the skull. What occurs about the broken bones, when the patient survives a fractured base? Does union take place? and if so, by what medium are the broken bones united?

A few years back great doubt existed as to these points. You will find, for instance, great doubt expressed in M. Malgaigne's surgical anatomy, as to the possibility of union taking place in these fractures of the base of the skull. It so happened that M. Malgaigne was acquainted with only two cases in which dissection of the parts had been made after recovery from a fractured base. Finding in both these cases that the fracture presented no traces of union, M. Malgaigne thought it doubtful whether broken bones at the base of the skull were capable of consolidation.

And the doubt thus expressed remained unsolved for many years, preparations illustrative of the mode of union of a fractured base being but very rarely to be met with.

My researches in our hospital museums have been all but fruitless, and few, indeed, are the museums in this great metropolis which contain even a single specimen. The College of Surgeons possesses but one solitary preparation.

At this we shall not, however, be surprised, if we recall to mind how seldom it happens that a patient with fractured base recovers, and, moreover, how very unlikely it is that a Surgeon acquainted with the accident will have to examine the body at any subsequent period; for it unfortunately too commonly occurs that we altogether lose sight of many of our most valuable cases.

(To be continued.)

## ORIGINAL COMMUNICATIONS.

### SUGAR AND DIABETES.

By WILLIAM BUDD, M.D.

Senior Physician to the Bristol Royal Infirmary.

In the *British Medical Journal* of November 14, 1857, and March 13, 1858, under the heading "Sugar and Diabetes; a Case," I gave some account of a young man, named Snailum, who had been for some months under treatment for that disease in the Bristol Royal Infirmary, and who, after having steadily got worse under a diet from which sugar and its chemical equivalents were in great measure excluded, got steadily and very much better under a diet which included the daily consumption of a large amount of sugar in substance.

In the *Medical Times and Gazette* of May 1, 1858, in an article entitled "Some remarks on Sugar as an Article of Diet in Diabetes Mellitus," Dr. Bence Jones has done me the honour to make these two communications the subject of some lengthened observations.

Dr. Jones opens his paper with citing a case, by Piorry, in which a very large diminution in the quantity of sugar excreted by the kidney, followed the daily administration of four ounces of sugar candy. This, I imagine, is the same case as that to which I referred in my first paper, as being what finally determined me to try the sugar plan.

Among the particulars recorded in my narrative of Snailum's case, were the following:—

1. When he began the sugar treatment he was voiding from seven to ten pints of urine daily, ranging in specific

(a) Med. Chir. Trans. vol. ii. p. 105.

gravity from 1036° to 1044°. After having continued this treatment for five months, he was voiding from four and a quarter to six and a half pints of urine daily, of specific gravity, ranging from 1031° to 1040°; the last figure being observed, moreover, on a single occasion only. During the last six weeks of this period, the average quantity of the urine was five pints and a-half, the average specific gravity 1034° (a).

2. A week before the change of plan he weighed 107lbs. After having continued the plan for five months, he weighed 130½lbs.

3. Before he began to take sugar he was confined to his bed from weakness. After he had taken many ounces daily for five months, he had so far recovered his strength that he walked on one occasion nine miles on a stretch without fatigue.

4. Before he gave up the old treatment his skin was dry, his tongue dry and brown, his pulse frequent, and he was harassed by cough and pain of the chest. Under the new treatment these symptoms speedily and entirely disappeared.

These results, it will be seen, are not only large, but precise. A gain of more than twenty pounds in weight, and a recovery in strength, enabling a man who could not leave his bed from weakness to walk nine miles on a stretch, are facts about which there can be no mistake. That such results should have occurred in a diabetic patient who was eating from six to twelve ounces of sugar daily, was considered by many eminent persons who saw him while he was under treatment, and by the still greater number who watched the progress of the case, to be deeply interesting, whatever might be the interpretation of the facts (b).

I may add here what was not stated in my papers, that with one or two trifling exceptions, no medicine of any kind was given to interfere with the simplicity of the treatment.

In laying these facts before the Profession, I purposely abstained, on philosophical grounds, from entering into any speculations regarding them (c).

I was still more careful not to make the case the occasion of any recommendations. For reasons which will be easily appreciated, I felt, in fact, especially anxious, that in such a matter every one should be left to his own judgment.

The facts recorded in my narrative being, in precise terms, those which have just been recapitulated, Dr. Jones introduces the most important among them to the readers of the *Medical Times and Gazette* in these words:—"The patient is considered by Dr. Budd to improve greatly, in consequence of this (the sugar) plan of treatment;" and, in another sentence, "the increase of weight is stated as being nearly twenty pounds" (d).

In subsequent passages Dr. Jones refers to the harm that is

(a) It is well known that the precise quantity of sugar eliminated can only be determined approximately, by taking the specific gravity and the quantity of the urine. Where the terms of variation are very wide, however, they cannot well be misinterpreted. In the present instance they were sufficiently so to show, as surely as if the urine had been analysed, that the quantity of sugar excreted by the kidney had decreased, notwithstanding the consumption of many ounces, daily, of sugar in substance. On this point, a writer of very high authority expresses himself in these words: "If by two or more of these tests (referring to the well-known chemical tests for sugar) the presence of sugar is established, it is not necessary to make any quantitative analysis: for the medical man, a sufficiently near approximation is obtained by taking the specific gravity of the urine. It is not even necessary to refer to Dr. Henry's tables, in which he gives the solid contents of diabetic urine of all specific gravities. All the information you can use you will obtain by comparing from day to day, or from week to week, the specific gravity and the total quantity of the urine passed in twenty-four hours."—*Animal Chemistry*, by H. B. Jones, M.D. F.R.S. (p. 115.)

(b) The following, among others, may be named as having seen the patient while he was under the sugar treatment: Dr. Symonds, Dr. Radcliffe Hall, Dr. Henry Frispi, Dr. Beddoe, Dr. Henderson, and Dr. Harley, of University College, London.

Some of these gentlemen were so surprised at seeing a diabetic man eating half-a-pound of sugar a-day, and presenting the appearance of robust health, that they were not content until they had verified the diagnosis by testing the urine for themselves.

(c) The precise words of the first three sentences of the very brief remarks which I appended to the case were these:—

"I have purposely abstained from burdening this narrative by any lengthened comments. There are few maxims in philosophy which are more entitled to respect than that which inculcates caution in drawing deductions from single instances. The striking result here obtained from this new mode of treating diabetes, must not only be repeated in other cases of the same kind, but must be sustained for a longer period in this one, before any general inferences can be safely founded upon it." In my second paper I maintained the same cautious tone.

(d) Dr. Jones adds, "in the first two months;" but if he will read my paper again, he will see that the increase of weight there recorded, refers to the date at which the paper was written, and that it had occupied, therefore, rather more than four months.

being done by my suggestion. As, however, I have made no suggestion—have *designedly*, in fact, abstained from making any—this phrase, as applied to myself, is a phrase without meaning. In illustration of "the harm that is being done," Dr. Jones refers to cases which are brought before him, in which the symptoms of diabetes have been much aggravated by the administration of sugar; but as what he says on this head consists merely of loose statements, unauthenticated by particulars of any sort, I need scarcely say that it is totally inadmissible as evidence in a scientific question.

The only part of Dr. Jones's paper which has any claim to this last character, has reference to two cases—one bearing date "1854" (the month and day of the month not being given), and the other bearing date Jan. 20, 1858. On these two cases, in which sugar was given—with various, but in the main, as it would appear, with opposite effect—I will venture to make a few remarks.

Of the first, the chief peculiarity is, that, while professing to be a record of chemical observations, it is entirely wanting in the precision which is the very essence of chemical data. The observations in question are divided into two series. In the first series the quantity of urine passed in the twenty-four hours is seldom given, and the vague expressions "sugar," "some sugar," "much sugar," occur where precise numbers should have appeared. In the second series, the ratio of sugar to the pint is carefully ascertained, but the quantity of the urine is absent throughout!

The endeavour to obtain greater accuracy in the second series only proved, therefore, to be a waste of power. Its object, Dr. Jones says, was "to determine more accurately the amount of sugar produced in the urine by the bread." But to attempt to determine this by ascertaining with elaborate care the ratio of sugar to the pint, when the number of pints passed is not forthcoming, is much as if one should attempt to determine the cubic contents of a given mass by taking its length with microscopic minuteness, while failing to give its breadth and thickness (e).

These deficiencies in quite fundamental points, strike the reader the more, from the contrast which they present in those respects to the few simple and precise results which Dr. Jones has quoted from Piorry at the head of his paper.

One point does, however, emerge from the observations made by Dr. Jones on his first case, and that is, that in a diabetic patient, fed otherwise on a purely animal diet, moderate quantities of saccharine matter (two ounces of sugar or four of honey) may be given at intervals for a day or two together, without causing sugar to appear in the urine. This result is not without its importance, although in what way it helps the writer's general argument, it is not so easy to divine.

Under the circumstances, we have, perhaps, no right to complain that the case is deficient in all the particulars that most interest the Physician. Throughout the narrative no data are given to show in what way the health and general condition of the patient were affected by the changes of regimen to which she was subjected. The only fact bearing at all on these all-important points is set forth in the solitary, and, for a scientific production, somewhat singular record, "She had not gained in weight above one pound." (*Sic*.)

This record, whatever may be meant by it, embodies the result of six weeks' trial of a purely animal diet, as measured by the weight of the patient.

The second case is more full, and the chemical data, as far as they go, appear to be accurate. Altogether they cover a period of twelve days. The general results are given in a table in the body of the paper. From the tabular statement as first published it would appear as if sugar, in the quantity of eight ounces, had been given during seven days. From a list of *errata* inserted in the ensuing number of the *Medical Times and Gazette*, we learn, however, that this substance was only given during three days! (f)

(g) It is true that Dr. Jones apologises for this fundamental omission by stating that the register of the quantities has been mislaid. But that being the case it might have been worth considering whether the other results were worthy of being recorded in a paper which rests its claims to attention on the superior accuracy of its proceedings. Under the circumstances, the phrases, "sugar," "some sugar," "much sugar," would have done very nearly as well as the more precise indications of Soleil's Saccharometer.

(f) There is a serious discrepancy still remaining between the table and the context which requires explanation. In the report for the 3rd April, this note occurs:—"She complained of the sugar, and the experiment was discontinued." According to the table the sugar had been left off two days before this.

An experiment confined to a single case, and extending only over three days, is a narrow basis for a physiological induction.

This, however, is far from being the only objection to which the case is open.

It is a principle too elementary to need enforcing here, that in attempting to estimate in a given result the effect due to the introduction of a new element, it is essential, as far as this can be done, to keep the old elements constant. Especially is this true of elements known to have great influence on the particular effect which is the object of research.

In endeavouring to determine the effect which the administration of sugar might have in diabetes, on the quantity of sugar excreted by the kidney, it is above all things important that the quantity of *bread* consumed by the patient should not vary.

On casting the eye over Dr. Jones's table, it appears, however, that his patient took on one of the twelve days 5 ounces of bread, on another 8½ quarter ounces, on another 7½, and on others 7!

In addition to these causes of disturbance, we are informed that during the same period she had a violent hysterical fit, and an attack of urgent diarrhoea; and that she also took *opium*, ether, and other medicines.

It would be strange to find in data such as these the elements for the solution of a difficult physiological problem.

Taking the facts, however, for what they are worth, the general result, stated in precise numbers, is this: The days on which sugar was given, when added together, amounted to three. During these three days the average quantity of sugar excreted by the kidney exceeded the average quantity excreted on the five days when sugar was not given by 1153 grains; but as, for every 1153 grains of saccharine matter eliminated, as much as *eight ounces* were taken in, the proceeding must have issued, supposing the surplus to have been appropriated, in a daily gain of many thousand grains of respiratory aliment to the system. So that, as far as chemical grounds go, the case offers a strong confirmation of the principle of administering sugar in diabetes.

I say, "as far as chemical grounds go," because I am particularly anxious to guard myself from the imputation of supposing that, in the present imperfect state of science, chemical data, taken alone, can ever be safely trusted as guides for practice.

In the present instance, I need scarcely add that the saccharine regimen was not continued long enough to enable the practitioner to judge of its effect on the general condition of the patient. Dr. Jones has, it is true, given the weight of the subject for every day that figures in the tabular statement. The precise object of this, however, does not appear, as it is evident enough from the facts, that these weights may represent something quite other than the effect of the sugar.

The sum of Dr. Jones's investigations appears, therefore, to be this:—As far as can be judged from the evidence which he has placed before us, both of his cases testify in favour of the sugar plan. As, on the other hand, the cases are only two; as the experiments were continued for a very short time; and, lastly, as both cases are chemically as well as medically very imperfect, they cannot be counted for much either on one side or the other.

In more than one passage of his paper Dr. Jones speaks of my results being answered by the opposite results which he and others have observed as the consequence of the same plan of treatment. If I were to adopt his method of philosophising, I might say in return, that the results obtained in his second case are answered by the precisely opposite results obtained by Piorry; or that his second case is answered by his first; or, to take yet another instance, that the disappearance of sugar from the urine in his first case, on the institution of a purely animal diet, is answered by the case published by Andral, in which, under the same regimen, the sugar excreted by the kidney, after undergoing a temporary diminution, gradually rose from 27 grammes to the pint, to the enormous ratio of 49 grammes to the pint; or by the still more remarkable instance recorded by the same eminent Physician, in which a diabetic patient, who lived "entirely on flesh," voided, notwithstanding, nearly 20 ounces of sugar daily.

But I have always been taught—and these very illustrations establish the position—that facts are self-subsistent. One argument may be answered by another, or a theory by a

theory; but to speak of a fact being *answered* by a fact, is to utter a logical solecism.

The facts which have just been referred to are only a few among the many that might be cited, which show, in the most striking manner, that the true law which in diabetes regulates the relation borne by the quantity of sugar excreted, to the nature of the ingesta, yet remains to be discovered. And it is not difficult to see that if this law is to be made out, it must be as the reward of a much larger induction than any that has hitherto been attempted, and of a very different order from that of which Dr. Jones has here given us an example.

My present purpose, however, is not so much with Dr. Jones's paper, as to take the opportunity which this discussion affords, of communicating some particulars of another case of diabetes, in which, under circumstances the most unpromising, results, in some respects, even still more striking than those which were observed in the case of Snailum, followed the adoption of the same line of treatment.

Elizabeth Hilliard, a widow, aged 53 years, a diminutive person, and already for a considerable time the subject of diabetes, was admitted on the 11th of March, 1858, into ward 2 of the Bristol Royal Infirmary, where she still remains under treatment.

The symptoms which first arrested her own attention were frequent calls to make water, with great increase in the quantity passed, which amounted to several quarts daily; insatiable thirst, progressive weakness, and loss of flesh; and severe pruritus of the external parts. These complaints had come on rather suddenly about fifteen months before admission, in immediate sequel to severe mental anxiety. During the interval, she had been for some time an out-patient of the Infirmary, and subsequently, and for a period of rather more than two months, a patient at the Clifton Dispensary. She had never before, within her recollection, had any illness requiring Medical attendance.

When admitted her debility and emaciation were extreme. The degree of wasting may be estimated by the fact that when placed in the weighing machine she was found to weigh only sixty-five pounds. She was unable to stand or even to sit up in bed, without being supported. The skin was peculiarly harsh and dry; the pulse 100. On the day after her admission, and for many subsequent days, the tongue was dry and brown. Her nights were much disturbed by calls to make water, and her thirst was very great. There was a hectic flush on the cheek, and she was much harassed by frequent dry cough and by pains of the chest. Although there were no physical signs of lung-deposit, my impression was that she was most probably the subject of tubercle.

She had reached, in fact, what Dr. Prout describes as "the last and usually the briefest" stage of diabetes.

On the day after her admission she was placed for five days on the ordinary (technically, "the middle") diet of the house. No medicine was given.

During these five days she passed six pints of urine daily, of sp. gr. 1040°.

On March 17 she was ordered to take ten ounces of the best white sugar daily, and was put on the following dietary:—

Bread (common) 12 ounces; meat 12 ounces; butter 3 ounces; greens 8 ounces; beef-tea 1 pint; sherry 4 ounces,—to all which, two eggs were added on March 22. An ounce of cod-liver oil, which she took daily from the day after her admission until April 16, may also, I presume, be fitly included in this list.

On March 18, twenty-four hours after the adoption of this scheme, there was an increase of three pints in the quantity of urine passed, which now amounted to nine pints, of sp. gr. 1040°. Her thirst had also increased, and she was weaker. The pulse had risen to 116. In short, she was in all respects worse.

On the 19th, under the same treatment, the quantity of urine fell to eight pints, and the specific gravity to 1037°.

As, with the exception of the sugar, the new dietary differed from that for which it was substituted chiefly in containing much less amylaceous matter, it was tolerably clear that the sudden aggravation of the diabetic symptoms was due to the administration of the sugar.

Under the idea that the fault might be, not in the principle, but in the application of it, I did not withdraw the sugar, but merely reduced its quantity from ten ounces to five.

As the patient complained much of inability to sleep, I, at the same time, ordered five grains of compound soap pill to be taken at night. I may add that as this prescription seemed to answer it was continued for the next ten days, when it was left off on account of constipation.

The opium probably had something to do with the sudden improvement which now occurred in the quality of the urine.

Be this as it may, the quantity of this secretion fell on the following day to five pints,—its specific gravity continuing at 1037°. On the next succeeding day five pints were again passed, of specific gravity 1036°.

Between this date and the 30th March, the urine fluctuated in quantity between five and a-half and six pints, and in specific gravity between 1037° and 1040°.

The only changes worthy of note in the patient herself were, that the tongue had become moist, and that she was somewhat stronger. She was able to sit up in bed, and could stand for a few moments without support. She relished the sugar, and it appeared to agree with her. Nevertheless, on being put in the weighing-machine on the 30th March, she weighed only sixty-four pounds; so that in sixteen days she had lost one pound.

As from the history she gave of herself there was reason to believe that her loss of flesh for some time prior to her admission was more rapid than this, the true interpretation of this fact probably was, that some check was already being put to her downward progress.

In the next fortnight she steadily improved. On the 13th April, this note occurs in the journal of her case:—

"Weighed yesterday, 69½ lbs. Pulse 76; tongue clean and moist; skin soft and moist, having entirely lost its original harshness; gains strength daily; appetite good."

She was now sitting up for an hour or two every day. The cough and other chest symptoms had entirely ceased. The only change made in the treatment during this last interval was, that on the 30th of March the sugar was increased to six ounces daily, and on the 3rd of April a quinine mixture was ordered to be taken three times a-day. Half a pint of bitter beer was also substituted for the sherry. The urine, meanwhile, continued pretty steadily at six pints, its specific gravity ranging from 1035° to 1040°.

On the 20th—that is, seven days later—there is this further note:—"Weight, 72 lbs.; better in every respect; remains up six hours every day, and walks about."

In the week following she scarcely held her ground. In the early part of the week some relatives came to visit her, with whom she was on bad terms. A violent altercation ensued, and she was much agitated during the night. On the day following the urine had increased more than a pint, and the specific gravity had risen several degrees. She continued to be very poorly for some days, and on the 27th she weighed only 71½ lbs., being half-a-pound less than the week before. Annoyances of the same kind have occurred to her several times since, and have always been followed by a similar change for the worse.

On the 24th the quinine was left off, and twenty minims of the dilute nitric and muriatic acids, in equal parts, were given three times a-day, instead. This last medicine she still continues to take.

On the 27th of April the sugar was increased to eight ounces, that is to say, to within two ounces of the quantity first prescribed. It is deeply worthy of remark that without any other change being made, the urine on the day following, instead of increasing, showed a large diminution. On the 25th, 26th, and 27th, she passed 6 pints on each day; the respective specific gravities being 1035°, 1036°, and 1034°. On the 28th of April she passed only 5 pints, of specific gravity 1034°. On the 29th, 4½ pints, of specific gravity, 1035°, and on the 30th, again, 4½ pints, of specific gravity 1034°.

On the 4th of May, her weight had further increased to seventy-three pounds: a point at which she still remains. Beside this, she is in all respects very much better. The tongue is clean and moist, the appetite is good, the bowels are regular, and the thirst is moderate. She is generally up the greater part of the day, and on fine days often passes much time in the infirmary garden. On the 3rd of May, after having spent a good part of the morning in that way, she went out, on foot, to visit a sick relative, and walked more than half-a-mile without fatigue.

During the last ten days the urine has only once reached

six pints: the average quantity for the other nine days being somewhat short of four pints and a-half; and the average specific gravity for the whole period 1034°.

One change has occurred in the patient while under this treatment, which deserves to be specially mentioned on account of its physiological interest. When she came into the Hospital she was almost as dark in complexion as persons affected with bronzed skin. As the treatment proceeded she became visibly lighter, week by week, to such a point that it would be difficult to recognise her now as the same person.

The speedy subsidence of the chest symptoms equally deserves to be brought into prominent notice. We might, no doubt, attribute this to the opium employed. I would observe, however, that a precisely similar result occurred in the case of Snailum, to whom no opium was given. I withhold all comment from these facts, at present, beyond suggesting that they may both very possibly be eventually found to possess an interest extending far beyond the present topic.

In summing up the results detailed in the preceding narrative, the leading facts appear to be these:—

1. In the interval between the 30th March and the 4th May the patient gained nine pounds (a gain representing one-seventh of her whole weight), with a proportionate recovery of health and strength.

2. During the same period she was taking from five to eight ounces of sugar daily.

And 3. Notwithstanding this large daily consumption of sugar, instead of an increase, there was an abatement of the proper diabetic symptoms.

In connexion with these results, I shall confine myself at present to two remarks.

The first is the very obvious one, that whatever may happen in other cases, or whatever may be the ulterior issue of this one, these facts will abide.

The second is, that as it is impossible to suppose the sugar to have been without effect, the results here detailed must have been obtained either in consequence of its administration or in spite of it. If in consequence, then the facts are of extreme importance; but if in spite of it, they are scarcely less remarkable in the extreme opposition they offer to all we have hitherto been taught on the subject.

In regard to this point, Dr. Prout, who is confessedly one of the highest authorities in these matters, uses these remarkable expressions: "Every variety of the saccharine principle in its crystalline form, is absolutely inadmissible as an article of diet in diabetes. This rule excludes, therefore, at once all fruits, whether subacid or sweet, as well as every compound, natural or artificial, into which sugar enters. The practical importance of this rule is so great, that I am doubtful if it be neglected whether good can be obtained from any plan of treatment" (g).

But here we have a diabetic patient eating from five to eight ounces of sugar daily, and not only rallying from a stage of the disease which Dr. Prout describes as being all but irretrievable, but adding in little more than a month a full seventh part to her weight, and becoming the while (what perhaps is most extraordinary of all) gradually less diabetic.

Antagonism more extreme than this it is impossible to conceive.

And there cannot, I think, be a more complete vindication than is to be found in it of the course I have taken in laying these facts in a simple manner before the public.

I may add, in conclusion, that in publishing them I do so in the full confidence that they will be regarded by the Profession generally as not without interest, in spite of attempts to disparage them, from whatever quarter they may come. Of this, at any rate, I feel very sure, and that is, that all such attempts will fail of their object when they come before us, seasoned by jests on Homœopathy, having neither point nor good taste to recommend them.

P.S.—Since the foregoing notes were sent to press, this patient has continued steadily to improve. Her weight, now (May 18), is 75 lbs. During the last five days her urine has varied in quantity from 4 pints to 4½ pints; in specific gravity from 1034° to 1037°. She is still taking eight ounces of sugar daily.

# AN INSTANCE OF THE OCCURRENCE OF POISONOUS EFFECTS FROM ARSENIC

FOR THE FIRST TIME WHEN REPEATED  
AFTER THE ADMINISTRATION OF ANTIMONY DURING THE  
INTERMISSION OF ITS USE.

By JOHN ELLIOTSON, M.D., Cantab. F.R.S.

ON the 5th of July, 1856, a communication by me was honoured with insertion in the *Medical Times and Gazette*, illustrating the greater power of antimony, unaided by other measures, over inflammatory croup, when given so freely as to render frequent visits of the Medical attendant advisable during the twenty-four hours, and its tendency to occasion tetanic symptoms when exhibited so freely, although I did not contend that such symptoms were requisite or desirable. Palmer, before he murdered Cook with strychnine, had attempted the crime with antimony; and, notwithstanding some gentlemen imagined that he gave antimony first in order to prepare the system for the deleterious effects of strychnine, I said—

"There is no reason to suppose that he had any deep views of preparing the system for the action of strychnine, which is potent enough without preparation, or of rendering the detection of strychnine by the chemist more difficult, which is not known to be a fact. His course appears to have been simple enough—to attempt to murder Cook by antimony, as he probably had murdered his other victims—and, not succeeding so soon as he anxiously desired, to resort, at the last moment, to strychnine, with which also he failed, till, on the Tuesday night, he gave it again."

Upon the question—whether antimony renders the body more easily affected by strychnine—I did not enter. But in the following case the effect of arsenic may have been increased by the previous exhibition of antimony.

On the 24th of last October I visited, in consultation with Dr. Hamilton Roe, a middle-aged lady suffering from chronic rheumatism of the hands, feet, and some other joints, after the failure of excellent treatment. I recommended a trial of arsenic, which has long enjoyed a deserved reputation in such cases when little or not at all inflammatory. In chronic diseases it has always been my habit to begin with small doses of energetic medicines, whatever may be the extent to which there may at length be a necessity for augmenting them. She took at 10, 4, and 10 o'clock, one minim of the liquor potassæ arsenitis, for three days; then two minims each dose for three days; then three minims each dose for three days; and ultimately four minims every dose until the 25th of November, without nausea or any other inconvenience, but with a very great diminution of the rheumatism, and I did not visit her again till the 7th of December. I understood that in the meantime she had been attacked with bronchitis, which was successfully treated by Dr. Roe with the potassio-tartrate of antimony only, in doses of a grain, given at first every four hours, and afterwards less frequently, till eight grains had been taken at the end of four days. It had occasioned temporary nausea and depression. She was quite free from bronchitis, her rheumatism remained at the same point of improvement as when I last saw her before the attack of bronchitis, and she appeared to have the same strength and general health. The arsenical solution was, after an intermission of twelve days, and the omission of antimony for eight, recommenced, but in a dose of two minims only. On the fifth day of this dose, taken as originally three times a-day, she lost her appetite and strength, her face became pale, she had a sense of weight after eating, nausea, redness of the eyes, and great nervousness. I was sent for. The arsenic was at once discontinued, and those effects ceased.

On the 16th it was resumed in the last quantity, but discontinued in three or four days for the same reason as before.

On the 29th, as all discomfort from the arsenic had ceased for several days, and she still suffered from rheumatism, though greatly improved with the exception of one knee, the rheumatism of which was inflammatory, we repeated her

medicine in the same quantity of two minims three times in the twenty-four hours; but she could not bear it more than two or three days, notwithstanding her great anxiety to take it on account of the good which it had done her.

Whether the first disagreement of the arsenic with her arose from the previous exhibition of the antimony, I will not presume to assert, because the susceptibility to the influence of individual drugs occasionally changes. I have known the same person readily affected by mercury, who formerly resisted its influence; and one person, who, though a large and hearty man, could never take more than the sixteenth of a grain of iodide of potassium formerly without extreme depression, bear on a subsequent occasion doses of a grain perfectly well: and all this without any obvious reason. But, in the present case, the period of extreme susceptibility followed too quickly upon the previous tolerance, I think, for this change to be without some obvious circumstance; and there was an obvious circumstance, and a possible cause, in the free exhibition of antimony, some of which, I presume, still existed in the body; and, though the same might be true of the arsenic, this, it must be remembered, had never disagreed in the least. If debility had been left by the antimony and bronchitis, the increased susceptibility might have been ascribed to it; but, if it existed at all, it was inconsiderable, too inconsiderable, I fancy, to be regarded as the cause. Still, a positive conclusion appears to me impossible, and I have therefore detailed the facts after heading them as merely "poisonous effects from arsenic for the first time when repeated after the administration of antimony during the intermission of its use."

Conduit-street, Regent-street.

P.S.—April 27.—As my communication has not yet been printed, I take the opportunity of mentioning a circumstance which has come to my knowledge to-day. After my communication was sent upon the 12th instant, the lady was so desirous of taking the arsenic again, to secure still greater benefit, that she resumed it on the 14th, and, beginning with one minim each dose the first twenty-four hours, augmented the dose on the fourth day to four minims, which she has taken up to this time without the slightest inconvenience. This is an additional reason for presuming that the greater susceptibility was due to the antimony, which, it may be presumed, has now left the system.

## ON THE TREATMENT OF SEROUS EFFUSION INTO THE PLEURA.

By HAMILTON ROE, M.D.

Senior Physician to the Brompton Hospital, and late Senior Physician to the Westminster Hospital.

(Continued from p. 479.)

Mr. Evans thought this reasoning fair; we therefore submitted to the gentleman's father our reasons for thinking that the operation ought to be performed. They appeared to him so satisfactory, that he requested it not to be delayed. Mr. Evans made a short incision over the fifth rib, in the place where the grooved needles had been introduced; drew down the wound over the fifth intercostal space, and passed his trochar through it into the chest; on the withdrawal of the stilette clear straw-coloured serum, with some floccul, gushed out; we observed that very little air, much less than usual, entered during the operation, which we attributed to the lung expanding as it was relieved from pressure; the fluid withdrawn measured nearly six pints. He felt faint after the operation, but soon recovered; one grain of opium was given him that night, and two grains of calomel with a little opium were given him three times a-day for three days; it did not affect his mouth, but as he appeared weak it was discontinued; at the same time, he was directed to make use of a very spare diet. On Monday, the 20th of March, I saw him again, he felt considerably better, and much relieved in his breathing, but weak; respiration was audible both anteriorly and posteriorly on the left side, but it was very deficient; the heart had moved a little to the left, but was still displaced; there was dulness in the lower part of the chest only to the height of about three inches. Mr. Evans

and I now agreed that he should be dry cupped, and afterwards blistered, and that he should still remain on low diet. Between the 20th of March and the 1st of April dry cupping was performed twice, and two blisters were successively applied on the back, and front of his chest; from the last, however, he suffered so severely, that we abandoned the intention of blistering him again. On the 1st of April he came to London, his heart had moved considerably to the left side, the respiration had become more audible, but the dulness continued up to the same level at which it was on the 20th; his pulse was 120, feeble, and his countenance was pallid; he was now allowed to take meat, and a little wine twice a-day. Tincture of sesqui-chloride of iron was prescribed to be taken three times a-day, and exercise in an open carriage; on the 4th of April his general appearance had greatly improved, he was strong enough to walk a little, and his food had not disagreed; the tincture was continued, and on the 8th of April he was able to go to Bangor, where he quickly regained his health, but the sudden change from mild to very cold weather after he had been in Bangor a fortnight, reproduced his disease, and obliged him to return home to Liverpool, where I saw him on the 26th of April in consultation with Dr. Dickenson and Mr. Bickersteth: we all agreed that he should be tapped again without delay: a considerable quantity of serum was then withdrawn from his chest by Mr. Bickersteth; he remained in a very weak state for some time, under the care of Dr. Dickenson. The fluid again accumulated, but this time it soon made an opening for itself in one of the intercostal spaces below that through which it had been withdrawn, and continued to discharge itself daily.

Dr. Dickenson's report was, "that from this time he continued gradually and steadily, though slowly, recovering his strength and health, till he went to Madeira in the last week of September; his cough had entirely ceased, and his expectoration, which never had been great, had for some time disappeared; and he was gaining flesh considerably, had a good appetite and refreshing sleep, and in all respects was proceeding satisfactorily with the following exceptions: his pulse kept up to nearly 100 per minute, and increased slightly in frequency towards night, when he had a little hectic flush; he had rather profuse night perspirations, and there was a continual discharge of purulent matter from the fistulous opening in the side, amounting to perhaps three or four ounces daily. His treatment was good diet, with bitter ale; quinine, iron, and when the weather permitted it, outdoor carriage and walking exercise. Dreading the effects of our severe climate, I recommended his removal to Madeira."

He there placed himself under the care of the late Dr. Ross: lived well, and took a good deal of exercise on horseback. He returned home in May, 1855, very much improved in health, but with the fistulous opening still discharging a very small quantity of purulent matter. He returned in the autumn to Haylebury, resumed his studies, and after passing his examinations in a highly creditable manner, went out to India in the autumn of 1856; the fistula having closed just before he left England. I have reason to believe he is now in good health.

The following cases afford good illustrations of the value of paracentesis as a remedial agent in the variety of serous effusion into the pleura.

**Case 4.**—W. Cormack came under my care at the Brompton Hospital in October 1845, supposing himself labouring under consumption, though without its aspect. A superficial examination disclosed considerable pleural effusion of the left side. He was pallid, and much enfeebled; a brass-finisher by trade, having enjoyed good health till the 7th of the previous June, when he had a slight sore-throat, and since that time his health had declined. His breathing had gradually become distressed after exertion. A short cough had come on, unattended with expectoration, succeeded by progressive emaciation, debility, and night perspiration. A month subsequently, slight epigastric and infra-scapular pains were felt, continuing for six weeks, and then subsiding. During the last month the patient thought he had gained flesh, his appetite having been always good. The left side measured three-quarters of an inch more than the right, and was motionless, and sounded dull up to the clavicles on percussion. The breathing was somewhat tubular in the upper part of the chest, and indistinctly heard inferiorly. The heart sounds and impulse were perceived to the right of the ensiform cartilage. No egophony could be detected.

He was admitted into the Westminster Hospital on the 22nd of October, and was tapped on the 28th, when six pints of clear straw-coloured serum were taken from the left pleura: sp. gr. 1.025, alkaline, and coagulating when boiled with nitric acid. Air entered freely during the operation; next day respiration could be heard, though feebly, over the left side. Doses of calomel and opium were given him every six hours, but on the 1st of November he seemed so feeble that these medicines were omitted, and he was put on full diet, and was directed to be dry cupped all over that side as often as he could bear it. On the 11th the heart had moved considerably nearer towards its natural situation; respiration was heard over the upper part, but still obscurely at the lower part of the lung. From this time he improved steadily, and was discharged in good health on the 18th of December. He is now in good health.

**Case 5.**—I was requested on the 26th of January, 1848, to see a young lady, pronounced to be in a hopeless condition by two of our best Physicians, and an eminent Hospital Surgeon; and after having been tapped in the chest three times, I had no expectation that I could do anything for such a case; but her father was so urgent for my opinion that I yielded to his wishes. I found a young lady, aged 14, thin, pallid, and very feeble, with dulness in the lower part of the left side of her chest, tympanitic clearness of the upper part; metallic tinkling, and amphoric breathing heard during respiration. The pulse was 120. She complained of cough, and nightly perspiration. It was clear that in her condition there was every probability of the fluid reaccumulating as fast as it was withdrawn, and that she could not bear many more tapings. On the other hand it was very improbable that she could get well if so much fluid and air were allowed to remain in her chest. Under these circumstances, it occurred to me that by establishing an opening through which the fluid might be drawn off daily, and by strengthening her system, a chance of recovery, perhaps the best chance, would be afforded to her; and accordingly I requested Mr. Wigan of Somerset-street, whose patient she was, to pass in a double-edged bistoury between the fifth and sixth rib, and the moment he had done so, I introduced a small piece of a gum-elastic catheter, closed by a stopper, and guarded by a button of ivory, into the wound, and secured it in its position by a piece of tape passed round her waist. This operation was performed on the 2nd of July, and two pints of turbid serum were withdrawn. On the next and following days she seemed in a state of fearful prostration. Her tongue now became aphthous, she was troubled with a diarrhoea that forbade strengthening medicine; she perspired a good deal at night, and a large quantity of sulphuretted hydrogen escaped with the fluid, which was drawn off daily. Her condition was so perilous, that we felt justified in making an experiment. On the 12th, she was rolled in blankets, and laid on a sofa in the garden. She was so much revived by this, that next day she was carried on a litter along the roads. In a couple of days more she was driven out in an open carriage. On the 21st she was taken twenty-six miles into Essex. Respiratory sounds began to be heard at the apex of the left lung in the beginning of August; the discharge, which had gradually become more and more serous, ceased early in September; and on the 29th, she went to Brighton. On the 28th of October she returned to London in good health, and without any contraction of the chest or deformity.—(See *Lancet*, vol. ii. 1851.)

**Case 6.**—Mr. Hamilton, a friend of Dr. Pollock's, had serous fluid removed from his chest. He was a well-made man, a Surgeon, aged 28. He was residing in Paris, enjoyed good health till Christmas, 1854, when he became languid, lost his appetite, and suffered from dyspepsia and confined bowels. On the 20th of March, 1855, he had a shivering fit, followed by great heat. Next morning he awoke with pain in the left side, but this soon subsided, and he had no idea that he had fluid in the chest, till Sir J. Olive examined him and told him so. On the 3rd of April, 1855, he was tapped by M. Trousseau, and three quarts of clear serum were withdrawn. In fourteen days he was up, and in three weeks he went out, took exercise, lived well, and soon perfectly recovered his health.

**Case 7.**—Mr. Jas. R., aged 50, called on me with Mr. Odling, of Devonshire-street, on the 27th of August, 1856, with unmistakable marks of effusion into the left pleura. He was then pallid and feeble. Mr. Odling stated that he had seen

him on the 16th of June, on his return from Oxford, suffering from great pain in the left side, close to the diaphragm, which was increased by motion, but that his breathing had not been affected. He had given him calomel and opium till he was salivated; he had then blistered him three times. On the 3rd of July he was seen by a Physician by no means likely to make a mistake, and who thought the pain rheumatic, and said there was no fluid in his chest. He tried change of air to Ramsgate, took hydriodate of potash, and afterwards the tincture of the sesqui-chloride of iron, but without any benefit. I advised tapping, on the grounds that he was in a very depressed condition, and therefore unfit to take mercury, and that there was no evidence of any active inflammation then going on. He did not like this advice, and went to several other Physicians, but he returned to me, and on Sunday, the 2nd of September, he was tapped to thirty ounces by Mr. Walton; and on the 11th, sixty-eight ounces more were drawn off. Good diet, and tincture of sesqui-chloride of iron were given him, but he became heated and feverish, and therefore the iron was omitted, and he was put upon low diet for a few days. When the feverishness had subsided he was dry-cupped frequently, and his diet was gradually improved. Various forms of iron were next administered to him, and he was directed to take horse-exercise and to use shower-baths. In a few months he recovered his health and good looks, and he is now perfectly well.

*Case 8.*—This man's case appeared to be so unfavourable for tapping, that we felt very unwilling to submit him to it, and were very doubtful as to its result. Charles Baker, aged 18, scrofulous, and consumptive-looking, a porter, residing at Brockley, near Lewisham, was admitted into the Brompton Hospital on the 13th of October, 1856, under the care of Dr. Cursham. His complexion was fair, hair light, figure spare, and he was below the average height. He stated that, though he had never been strong, he had not suffered from any serious ailment except measles, until about two years ago, when he felt severe pains under both scapulae and the lower ribs on the right side, for which he was salivated, on the supposition that they indicated disease of the liver, and he was kept under mercurial treatment for seven weeks. At the end of this time he went to the sea-side, and recovered sufficiently to resume his usual duties. He continued well till June last, when he had, as he was told, inflammation of the left lung, accompanied by a troublesome cough, hectic fever, and nightly perspirations. Since August he had been gradually losing flesh and strength, though his appetite was good. He was free from pain, his bowels were open, and he appeared free from fever. Tonics and a nutritious diet were given, and under this treatment he appeared to improve. Early in November the mammary region of the right side was observed to bulge out a great deal, and its lower part to be dull on percussion; at this part the respiration was deficient, and the vocal resonance increased. The right side measured 16 inches above the nipple, the left 15½; pulse 100, respirations 32. I examined him about this time at the request of Dr. Cursham, and found the above report perfectly correct. We consulted together as to the propriety of tapping him; but we feared to do it, neither of us having had experience of its effects upon such patients. It was true there was no well-marked dullness under the clavicles on either side; but I thought that I perceived a degree of dullness mixed with clearness, which indicated the presence of tubercles. He remained very much in the same condition till January, 1857, when the right side was observed to be more prominent than it had been, and the dullness to extend upwards as high as the third rib. A grooved needle was introduced, and clear serum followed; but Dr. Cursham and I felt it so doubtful whether tapping would be useful or not, that it was not performed; and Dr. Cursham was afraid to salivate him, thinking him to be an unfavourable subject for mercury. His time for remaining in the Hospital expired on the 21st of February; he then went to Lewisham, where his health considerably improved. Dr. Cursham saw him again on the 17th of March, and made the following note:—"The dullness extends an inch at least beyond the mesial line. Great dyspnoea, much cough, no improvement in any way. His breathing became more and more difficult, and on the 10th of April I took him into the Westminster Hospital at Dr. Cursham's request, and had him tapped on the 18th. Fifty-two ounces of clear serous fluid were withdrawn by a flat trochar from his chest, with great

relief to his breathing: no bad symptoms followed the operation, and on the 20th respiratory murmur was audible below the nipple. From this time he went on favourably till the 3rd of May, when he had an attack of fever, after which the upper part of the affected side became more prominent, and the respiratory murmur less distinct. Dry cupping was prescribed to be performed as often as it could be borne: on the 8th of May the breath-sound was deficient and tubular. From this time his breathing became more and more impeded; the dullness of the right side of the chest was observed to extend more upwards. Nevertheless, his general health and appearance improved. Early in June he was tapped a second time, and ninety ounces of clear, but dark coloured serum were abstracted, and a large blister was placed on his chest. He had had for some weeks a scrofulous inflammation of the ulna, near the elbow-joint; this soon became so much worse as to require attention, but all his pulmonary symptoms ceased; the fluid was not re-secreted, and in three weeks from the last tapping he was advised to go into the country to recruit his health. I have heard that he was obliged to go into Guy's Hospital on account of the state of his ulna, but that he had no return of the effusion.

*Case 9.*—Miss P., aged 27, caught cold in the latter part of the month of November, and felt a sharp pain in her left side; but it only lasted a few minutes, and then went away. Her appetite and strength failed, occasional cough came on, and she found that she could not stoop without losing her breath, neither could she lie on her right side. She consulted Dr. Frederic Bird, who detected fluid in the left pleura. On Thursday, the 17th of December, 2½ pints of clear serum were removed from her chest. Relief followed immediately, she was down stairs in the drawing-room on the following Tuesday, and in a month rode on horseback, never having had any bad effect from the operation.

*Case 10.*—On the 24th of March last I was requested to meet Dr. Elliott, of Denmark-hill, in consultation on the case of a patient of his, who was suffering from fluid in the left side of his chest. This gentleman was about 28 years of age, thin, very pallid, and generally out of breath; his left side was extremely dull from the clavicle to the margins of the ribs; his heart was felt beating a little to the right of the sternum, and in the epigastrium. No respiration could be perceived in the left lung except at its base, nor was egophony heard. His breathing was very much embarrassed by the least movement, and his pulse was feeble and rapid. He stated that, though not strong, he had not been laid up longer than three weeks; that he felt unwell, but did not know what was the matter with him, till Dr. Elliott examined him on the 11th of March, and found a very small quantity of fluid in his left pleura. From that time his breathing daily became worse, the indication of the presence of fluid gradually more marked.

It was clear that the fluid could not have been in his chest more than a few days; the absence of bronchial breathing showed that the lung had not undergone much compression. We therefore concluded that the quantity of fluid could not be great, that the vesicular portion only of the lung had been temporarily consolidated, and therefore that it was a favourable case for operation.

Next day, Dr. Elliott, Dr. Nicholls, his partner, and I, met at the gentleman's house. The operation was performed, and a little more than thirty ounces of high-coloured serum were withdrawn, which coagulated into a thick jelly on cooling. His breathing was immediately relieved. He was kept on low diet, dry-cupped frequently, and in a week from the day on which he was tapped respiratory murmur was heard all over the left side. The heart was felt beating in its natural situation; but there was still dullness at the very lowest part of the affected side, showing that there was still some fluid in it. His breath, however, was improving, the symptoms of fluid were gradually disappearing, and he was regaining strength when I last heard of him.

I have now given ten cases, in four of which tapping once performed cured the disease, in four of which it required to be repeated, but in which it also effected a cure, without giving rise to a single bad symptom, and in one progressing so favourably that cure may be expected. I beg leave to assure the Society that I have not published successful cases, and kept back those which were unsuccessful. My object is to deduce just conclusions from the results of every kind of treatment to which this form of disease has been subjected; and therefore I have given all the cases in which paracentesis

has been performed under my direction, distinguishing those in which it was expected to be successful from those in which there was only a faint hope that it might be useful, as in cases where a large quantity of fluid had been a considerable time in the pleura. To these I have alluded in my former paper; but the necessary failure of the operation under such circumstances does not constitute a valid objection to its employment. For myself, I must say that the results of a good many cases have convinced me that tapping will cure most cases of this kind, if it be performed sufficiently early; and that even were salivation proved to be equally efficient in removing effused fluid, which it certainly is not, it is a much more hazardous, more painful, and more injurious mode of treatment. I am at a loss, therefore, to understand why it should be preferred to tapping, or what reason there can be for deferring so trifling an operation, when once the symptoms of inflammation of the pleura have been subdued. M. Trousseau has had great success in treating these cases, as I am informed, because he withdraws the fluid at once. I cannot, therefore, doubt that anything but time is required to remove the prejudices now entertained against the operation, and to introduce it into general use. The most cautious Medical practitioner may surely feel justified in having recourse to it, when he finds that the remedies he is employing fail, or cease to produce a diminution of the effused fluid. To insure the success of the operation, it will in all cases be advisable, and in some necessary, to keep the patients upon whom it has been performed on low diet for ten or fourteen days, and to dry-cup their chests frequently.

Of the second subdivision of this variety of slow effusion with latent pleurisy, where the quantity of fluid is small, and the inconvenience produced by its pressure is slight, it is not necessary to say more than that such cases are of frequent occurrence, and that they are generally curable by the ordinary means used to improve general health, as open-air exercise, a generous diet, and tonics, especially iron, the tincture of the sesqui-chloride being the preparation which seems most suitable.

##### TREATMENT OF STRICTURE NEAR THE URETHRAL ORIFICE.

Two cases of troublesome stricture, close to the orifice of the urethra, have recently been under the treatment of Mr. Teale in the Leeds Infirmary. The subject of the first was a young man, aged 20, in whom the stricture had existed several years. Mr. Teale adopted the plan of cutting the stricture freely through, in the median line below. The skin and the mucous membrane were then stitched together on each side. The parts healed well, and a permanent oblique opening of good size was secured. The subject of the second case was a man, aged 53, in whom the same treatment was adopted, with an equally good result. Strictures at the meatus, although rare, are, when they do occur, usually very troublesome. Their most frequent causes are, phagedæna of the gland, or urethral chancre. The plan adopted by Mr. Teale in the above cases appears to be a very simple and effectual one. We have often known the most persevering treatment of these strictures by dilatation end in disappointment.

##### REMOVAL OF A NEEDLE FROM THE KNEE-JOINT.

A young woman, aged 22, was admitted into the West Norfolk Hospital a short time ago, having run a large darning-needle into the right knee-joint. The limb was first placed in a Macintyre's splint, and a small incision was then made over the needle, at the inner side of the joint. The needle was easily reached, and was withdrawn in two portions. The limb was carefully kept quiet on the splint, and no inflammatory symptoms worth mention followed. The girl was discharged quite well three weeks after the accident.

##### STOMATITIS PRODUCED BY CHLORATE OF POTASH.

Amy Wasford, aged 3, admitted with pustular ophthalmia and a great intolerance of light on March 9. She had been troubled with more or less of the same affection from early infancy. Ordered ten grains of chlorate of potash in an ounce of water three times daily. Much improvement resulted both in the condition of the eyes and in the general health, and as there was no evidence of disagreement on the part of the medicine, it was continued in the large dose first prescribed. She attended on March 16, 23, 30, April 6, 13, 20, 27, May 4, and 11. Several times the eyes had seemed almost well, and then, owing most likely to the unfavourable weather and continued easterly winds, they relapsed. Her mother considered that the child's appetite and general health had been very greatly improved by the remedies. From having been feverish and restless at nights she had got to sleep well and soundly. The medicine which had been throughout regularly taken and in full dose, never seemed to disagree in any way. On May 11, the dose was reduced to five grains. On May 18, she came with a very sore mouth. The saliva dripped from her lips, there were numerous follicular ulcers on the tongue and inside of lips, and one large one occupied a surface the size of a shilling on the back part of the dorsum of the tongue. The salivary glands were enlarged and tender, and the mouth full of saliva, although the pyalism was not extreme, nor were the gums sore. In this latter respect and in the existence of the larger ulcers on the tongue, the stomatitis differed from that caused by mercury. The eyes were nearly well.

##### AMPUTATION AT THE SHOULDER-JOINT FOR FIBRO-PLASTIC TUMOUR OF THE HUMERUS.

Mr. Holthouse has just had an interesting case under his care in the Westminster Hospital, in which amputation at the shoulder-joint was rendered necessary by a large tumour, involving the upper third of the humerus. The patient was a healthy-looking man, aged 30, who gave the history of his having fallen down and struck the left shoulder in August last, after which he had much pain in using the arm. In October the pain had become such that he was obliged to give up work, and he was subsequently for several weeks in one of the Borough Hospitals. At this time no tumour could be discovered. When admitted into the Westminster, under Dr. Radcliffe and Mr. Holthouse, in February last, the existence of a large bony tumour beneath the deltoid was very apparent. The forearm was partially paralysed, and liable to attacks of neuralgia. Passive motion at the shoulder was free, and unattended by pain, but he could not raise the arm without assistance. On February 23 he was taken into the operating theatre, and having been placed under the influence of chloroform, exarticulation of the humerus was performed. The joint was found quite healthy. Some difficulty in the amputation was experienced, owing to the shaft of the bone having broken at the diseased part, in the attempt to lift it from the glenoid cavity. The tumour proved to be a growth of fibro-plastic structure surrounding the bone, and apparently springing from the periosteum and outermost shell of bone. The medulla was, however, infiltrated with a softer material than that which made up the bulk of the growth. Its microscopic structure was carefully examined by Mr. Christopher Heath, the Demonstrator to the Hospital, and no elements resembling those of cancer found. Unfortunately the man's death afforded an opportunity for confirming the opinion, as to its non-malignant nature by the evidence obtained at the autopsy. No secondary growths were found in any organ. The fatal result was due to gangrene of the wound, followed by pleurisy.

##### CONGENITAL DEFICIENCY OF ONE BREAST IN A GIRL.

A girl, aged 10, now attending as an out-patient at the Metropolitan Free Hospital, under the care of Dr. Staveley King, affords an example of a rare congenital abnormality, viz. the entire absence of one mammary gland and its nipple. It is the right gland which is wanting. The opposite one appears naturally developed. As is, we believe, usual in these cases, the lower serrations of the pectoralis major muscle are also deficient. There is no history of any of the child's relatives having had a similar abnormality, but her mother states that at

an early period of her pregnancy she saw a woman who had had an operation performed on her breast, and that the circumstance made a vivid and painful impression on her mind.

#### TWO SUPERFLUOUS EARS.

A little girl, recently under Mr. Birkett's care in Guy's Hospital, might have more than answered to Macbeth's requisition, "Had I three ears, I'd hear thee!" since she possessed no fewer than four aural appendages. The two superfluous ones were situated on the sides of the neck somewhat lower than the angles of the jaw, and were well developed as far as regards their external contour, and the possession of fibro cartilage. They had, of course, no deeper structures, and merely grew from the skin. Mr. Birkett had had the child under observation almost from the time of birth.

In connexion with these examples of congenital deviations from natural formation, we may mention that the curious in these matters may have an opportunity of seeing a case in which one lower extremity is nearly two inches longer than its fellow, by looking into Mr. Birkett's wards. The muscles in this case appear proportionately developed to the extra length of the bones.

## Medical Times & Gazette.

SATURDAY, MAY 22.

#### THE ROYAL MEDICAL BENEVOLENT COLLEGE.

EVER since the commencement of the effort to found this noble Institution, we have done our utmost to make known and assist in the objects of its indefatigable and benevolent founder, and have constantly urged our readers of every class, however divided on other points, to unite cordially in relieving their poorer professional brother, and in supporting his widow and orphans.

By the generous co-operation of the Profession, and the sympathy of the public, about £50,000 have been collected, and an annual income is subscribed which might supply the necessities and comforts of life to many deserving but unfortunate men, and educate a considerable number of orphans.

It would be too much to expect that so much could have been done without some difference of opinion as to the manner in which the money subscribed has been expended. Men will differ in opinion, and although they are striving to attain the same end, they will take different roads. So in the Medical Benevolent College there are subscribers who are dissatisfied with what has been done, and who think that the interests of the Institution would be furthered by the infusion of some new blood into the Council.

At the recent annual meeting of Governors of the College there was anything but a feeling of harmony displayed. All were unanimous in the benevolent desire to confer the greatest amount of good upon the greatest possible number of their suffering brethren; but there was a wide difference of opinion as to the best way of attaining the common object.

The questions raised at the meeting by the report of the Council were numerous. In the first place, there is a doubt, and the doubt has been strengthened by opposite opinions of

Counsel learned in the law, whether any portion of the funds raised by charitable contributions can be diverted to assist in defraying the expenses of the paying scholars, or "Exhibitioners." It is urged that the board and education of the sons of living medical men who are not in affluent circumstances were among the main objects of the College, and that the sum originally named as payable by the parents of £30 a-year should not have been exceeded, whatever might prove to be the real cost of those scholars. The Council reply, that by the 38th section of the Act of Incorporation they are compelled to charge the prime cost of each exhibitioner, and have, therefore, been obliged to alter the annual payment from £30 to £40.

Supposing the legal point to be decided in favour of the view taken by the Council, it is then argued that under economic financial management, the cost of each exhibitioner ought not to exceed £30 a-year. It is stated that the original estimate of £18,000 for the building has been unduly exceeded, as upwards of £45,000 have been expended, and many of the sums charged in the Treasurer's report against the school account are considered excessive. This is supported by a comparison with the expenditure and charges of the Royal Naval School.

These questions have been discussed at various meetings. but, unfortunately, the discussion has never been fully carried on to a satisfactory decision. On one occasion it was met by a vote of confidence in the Council; and at the meeting last week the Chairman took a most unwarrantable course in refusing to listen to gentlemen who spoke in favour of adjourning the meeting for a month in order that the Treasurer's report might be printed and circulated among the members, so that each particular might be fully considered. Any attempt to stop full and fair discussion is so contrary to the feeling of a British assembly that we cannot be surprised at the occurrence of a scene of considerable confusion and excitement. The ballot for the election of members of Council took place under circumstances which may inflict injury upon the College, unless a more conciliatory spirit be evinced on the 8th of June next, when it has been agreed to hold the adjourned meeting at the Freemasons' Hall.

On the whole it must be confessed that the dissentient party of the Governors of the Royal Medical Benevolent College have some reasonable grounds of complaint, and are, therefore, entitled to a fair hearing. Without ourselves entirely endorsing the opinion that the sum of £40 per annum is too high a charge for a boy's board and education, we cannot help recollecting that in the prospectuses issued at the foundation of the College, it was distinctly promised that the sum charged should be only £30; and many of the less affluent members of the Profession were no doubt induced to support the new scheme in consequence of the promise thus held out. The prospect of a cheap education for their sons was a legitimate cause for inducing many hard-worked practitioners to join the new College; and there was no more reason why the commodity should not be supplied at cost price to the subscribers, than in the case of the club-houses, where the articles are furnished to the members without the profits of the dealers. Nor is the complaint unreasonable, that the amount of good hitherto effected by the new College at Epsom is somewhat disproportionate to the large sums subscribed and expended. At all events, we think that the Governors have a full right to demand an ample and detailed statement of the manner in which the funds have been expended; and any refusal or hesitation in affording such a statement is likely to be interpreted into a cloak for mismanagement.

We must also, in candour, allow that the personal character of the complaining party is entirely in their favour, and that there is no suspicion whatever that any of them are actuated by other than the purest and most honourable motives. They are all sincere well-wishers to the College, and they consider (whether justly or not) that the result of their agitation will

be to give greater stability and prosperity to the Institution than it has hitherto attained. Now it appears to us that the remonstrances of these gentlemen, instead of being met by argument and softened by conciliation, have been usually drowned in clamour, or silenced by the votes of overwhelming numbers of persons, brought down to support the Council under all circumstances. Hence has arisen an amount of irritation which it is not difficult to explain, and hence the schism has been gradually spreading, until it actually threatens the well-being of the College.

To one proposed change, it is hoped that no serious objection will be made, namely, to the infusion of new blood into the governing body of the Institution. We are far from uttering a word of disparagement against any of the gentlemen of whom the present Council is composed; on the contrary, we think that great merit is due to them for their generous and disinterested services, and for the high state of efficiency to which the College has already been brought. But surely there can be no reason why new men should not occasionally be introduced into the Council, and bring with them from without the force of public opinion, which may make itself heard within. According to the present system, a certain number of new members of Council must be elected every year; but practically the object of this rule is defeated by the re-election of gentlemen who have already served, there being at present no rule against such re-election. In casting our eyes over the list proposed by the Council themselves, and that which is supported by the opposition, we find names of the highest respectability, and indeed several names occur in both lists; but on the mere ground that an infusion of new material adds life and vigour to every human institution, we would suggest the propriety of a compromise on the part of the Council, by admitting some at least, if not all, of the names proposed on the opposition list. Such a graceful concession would prove the sincerity of the Council and their friends, while it would go far to satisfy their opponents, and we earnestly hope that some such course will be adopted.

At the adjourned meeting it is desirable that both parties should come determined to display a conciliatory spirit; and it is only fair to observe, that at the last meeting the Council were in fault, by attempting to stifle discussion by mere noise. The dissentients, though comparatively small in numbers, had much reason and justice on their side; and the vehement resistance which they encountered has probably gained for them an amount of public sympathy which they might not otherwise have received.

### THE WEEK.

ONE can laugh at Sydney Smith, in his horror of gigs, jocularly maintaining that, as regarded the prolongation of human life, the invention of this description of vehicle had more than counterbalanced the discovery of vaccination. But there can be but one feeling of contempt for the ignorance of the dandy Democrat, Mr. Duncombe, who had the audacity to state in the House of Commons, that, although "cow-pox was a very good thing in its proper place," yet, everybody who heard of Jenner's statue, "spoke of it with ridicule and disgust;" and actually implored the House "not to pollute (!) and desecrate the ground (!) by erecting a statue there to that promulgator of cow-pox;" and this was listened to without rebuke in an assembly of men who owe their own unscarred visages, if not their very existence, to a man whose discovery has saved in each European generation more lives than were sacrificed in all the wars of Napoleon, more lives than the whole population of England; whose discovery has reduced the mortality from small-pox in Great Britain alone from 30,000 annually in a population of 11,000,000, to less than 10,000 in a population nearly three times as large! The example set by

the Prince Consort, and the sentiments expressed at the important meeting for the inauguration of the statue will, we trust, be felt as a rebuke by men like Mr. Duncombe, and not be lost upon the country.

Mr. De Morgan made a useful suggestion at the last quarterly Court of Governors of the Middlesex Hospital. He said that, although a large number of patients was sent from the neighbouring workhouses, nothing was awarded by the parochial authorities for their support, either annually or in payment for individual cases; and he suggested that the rule, as adopted at St. Bartholomew's, Guy's, and other Hospitals, should be pursued at the Middlesex Hospital, requesting the parochial authorities to pay for the support of patients sent in by the workhouse officials. The Lord Mayor, whenever he sends patients to St. Bartholomew's, or other Hospitals, from the Mansion-house, always makes an allowance for their support; and in all cases sent by the city authorities to St. Bartholomew's, 9d. a day is given for their board. It certainly seems advisable that such a system should be adopted in other Hospitals;—the parochial authorities could scarcely refuse to accede to such a request, were an application made.

The examination, just concluded, at the East India House has resulted in the appointment of twelve Assistant-Surgeons to the service of the Company. There were twenty-five vacancies, and only fifteen candidates presented themselves. This paucity of numbers is attributed to the short notice which was given of the proposed examination, the necessity of preparation on the part of the competitors rendering a somewhat lengthened course of study imperative. It is gratifying to find that so much employment is now offered to the younger members of our Profession; and that while merit is pretty sure of reward, the system of nepotism and favouritism, by which incompetent persons were formerly thrust into lucrative and responsible offices, is fast dying out, at least as far as the Medical service is concerned.

Two children of a manufacturer of "air-balls" of coloured India-rubber, have been declared by a coroner's jury, to have been "accidentally poisoned by the continuous inhalations of particles of deleterious powder, used in the colouring of air-balls." The father deposed that he used ultramarine-blue, Chinese red, and rose-pink, adding, "I did use Brunswick-green, but desisted when another maker told me he had poisoned his finger with it." The balls would burst occasionally during the process of inflation, and the powder would fly about the room like smoke. Sometimes the children would pick up a ball after it had burst, and the father had seen the powder about their mouths. It should be remembered that the children of those who buy the balls as well as of those who make them, may be poisoned in this way; but we suppose any attempt to introduce a clause into the "Sale of Poisons" bill, prohibiting the use of the poisonous pigments in the manufacture of paper-hangings or air-balls, would be looked upon by Mr. Tom Duncombe and the Pharmaceutical Society as an unpardonable interference with free trade and the principles of the British Constitution.

At a meeting of the Bedford Branch of the Medical and Surgical Association, held at Bedford, yesterday, May 21st, it was to be moved that no member of the Association should meet a Homœopath in consultation. If resolutions such as that alluded to were generally passed and acted upon throughout the country, the members of our Profession who are said to dally with the Homœopathic quacks would soon

be forced by their interests to adopt the course for which a regard for their own dignity and that of their Professional brethren seems not to be a sufficiently adequate motive.

A new Society, entitled the Playground and Recreation Society, has lately been instituted for the purpose of providing adequate means and facilities for the healthful and innocent recreation of the poor children in this metropolis and our large towns. A dinner in aid of the funds is announced to take place on the 1st of June next, at the London Tavern, when Mr. Charles Dickens will preside, supported by the Marquis of Clanricarde, Lord Ebury, Lord Haddo, the Right Hon. T. Sotherton Estcourt, and other influential noblemen and gentlemen. The efforts of this Society are directed in a proper course, and in the interests of sanitary improvement we wish that they may be successful.

### INAUGURATION OF THE JENNER MEMORIAL BY PRINCE ALBERT.

On Monday afternoon the Jenner Memorial erected in Trafalgar-square was duly inaugurated by His Royal Highness Prince Albert, in the presence of a large body of noblemen and gentlemen, including the leading members of the Medical Profession.

The memorial, consisting of a bronze statue, has been erected on the west side of the square, immediately adjoining that of General Sir Charles James Napier, K.C.B. It represents the immortal Jenner in a thoughtful mood, the figure being seated. The memorial, raised by subscriptions from all nations, including America as well as from the European states, was designed by Mr. Calder Marshall, R.A., and as a work of art it is excellent.

The statue having been uncovered in the course of the afternoon, at 3 o'clock His Royal Highness the Prince Consort arrived at the Royal College of Physicians in Pall-mall East, where it had been arranged that the ceremony of inauguration should take place.

Amongst those present were the Marquis of Lansdowne, the Earl Ducie, the Earl Stanhope, the Bishop of Oxford, the Bishop of Bath and Wells, Lord Ashburton, Lord Littleton, the Dean of St. Paul's, the Lord Mayor, Sir R. I. Murchison, Sir Henry Holland, Bart., Sir James Clark, Bart., Sir C. Lynch, Sir John Forbes, Sir John Rennie, General Sir J. Wilson, Governor of Chelsea Hospital; Sir J. M'Gregor, Bart., Mr. B. Botfield, M.P., Professor Fergusson, Alderman Salomons, Professor Browne, Professor Brande, Mr. F. J. Pettigrew, Mr. E. Stanley, President of the College of Surgeons; Mr. W. Lawrence, Dr. Elliotson, Dr. Hawkins, Dr. Copland, Dr. Alderson, Dr. Billing, Dr. Conolly, Dr. Watson, Sir Charles Landseer, R.A., Mr. D. Maclise, R.A., etc. etc.

The PRINCE CONSORT said, Gentlemen, I take the chair at this meeting, convened to commemorate the anniversary of the birth of Jenner, in order to do honour to his memory, and in order in common with you to acknowledge that inexpressible benefit, that inestimable boon which this great philosopher and philanthropist has bestowed on the human race. This discovery was not the result of accident, like many others, however useful they may be, but arose from long and thoughtful observation and reflection, to which a whole life had been devoted. Gentlemen, this country may be justly proud to number him among her sons, as no man has been able to save so many human lives as this man has been enabled to do. (Loud applause.) His contemporaries have testified their approbation and their feelings of gratitude to Jenner by several important public acts, but it was reserved to us not the less to show how highly we valued and appreciated his services in the cause of humanity, by erecting this statue. May it long be preserved to give the features of this benefactor of humanity to the people of ages and generations to come. (Loud and continued applauded.)

Mr. G. V. IRVING then read the following report from the Committee.

*Report of Committee, May 17, 1858:—*

"The merit of having been the first to assert the claims of

Edward Jenner to the distinction of a national and metropolitan monument, is undoubtedly due to his friend and biographer, Dr. Baron. It was chiefly owing to his exertions that a statue was erected in Gloucester cathedral, shortly after the death of Jenner; but he felt that no provincial monument would ever be a fitting memorial for one who had conferred such inestimable benefits on the whole civilized world; and that it was only in the metropolis of Jenner's native country that the grateful recollection of these could appropriately be recorded. These views were not only ably stated by Dr. Baron in the closing pages of his *Life of Jenner*, but were inculcated by him on every opportunity. To this Committee he rendered most valuable assistance in the earlier part of its proceedings; but we had too soon to deplore his loss, and can only express our regret that he was not permitted to witness the successful achievement of the object for which he had so ardently longed and laboured. Although it is believed that attempts were made on more than one occasion to carry out the idea of a metropolitan monument to the discoverer of vaccination, nothing practically effective was done previous to the autumn of 1850, when a number of gentlemen having learned that Mr. Calder Marshall, R.A., had designed a statue of Dr. Jenner, arranged a meeting at which a resolution was passed, 'That the labours of Dr. Jenner in the cause of humanity have never been sufficiently acknowledged, although his great discovery of vaccination has been of such universal benefit; and that immediate steps be taken for the erection of a suitable national monument to his memory.' Having seen Mr. Calder Marshall's model for a statue of this eminent philanthropist, a general opinion was expressed that if it was executed in bronze and placed in a proper public situation in the metropolis, it would form an appropriate monument; and, in accordance with this, a preliminary committee, with a view of raising subscriptions for the purpose, was immediately formed. Dr. Conolly having consented to act as chairman, and your reporter having been appointed honorary-secretary, they were requested to write to a number of influential persons and solicit their assistance and co-operation. The result of these applications was so favourable that in the month of December following the Committee assumed a permanent form. On the same occasion a new feature was introduced into the scheme, to which our ultimate success must in a great measure be attributed. It is contained in the following resolution: 'As the benefit of Dr. Jenner's great discovery is not limited to British subjects, but has extended to the whole civilized world, the Committee are of opinion that the subscriptions should not be confined to his compatriots, but means should be taken to permit persons of other nations to contribute, and that a number of distinguished foreigners be requested to act on the Committee.' This appeal was responded to in a manner which exceeded the most sanguine hopes of the Committee, and it soon numbered in its ranks eminent men from every country in the world anxious and eager to do honour to the memory of Jenner. Acting on a suggestion of the late Chevalier de Carro, whose successful exertions in communicating vaccination to Turkey and India are well known, the Committee succeeded in giving a concentrated force to this new element by recommending the formation of national sub-committees. America with her usual energy, early took the lead, and chiefly through the zealous activity of Drs. Jackson, Ware, and Warren, of Boston, and those of Drs. Dunglison, Nutter, and Wood, of Philadelphia, speedily transmitted subscriptions to a large amount. Russia also came forward in the most liberal manner. It is well known that during the long war in the beginning of this century, the reputation of Jenner was often sufficient to mitigate some of the misery which must attend such a contest, and that his name alone was, on more than one occasion, found to be a talisman powerful enough to obtain the freedom of prisoners. Something of the same character occurred in reference to this subscription from St. Petersburg. They had transmitted the first instalment before the outbreak of the late war. During its continuance all intercourse was, of course, suspended. No sooner, however, was it renewed on the return of peace, that they hastened to forward the balances which they had kept through all the asperities of the contest, as a deposit sacred to the great cause of humanity. Several contributions were also received from Professors Retzius, of Stockholm, Holst, of Christiania, and Schröder van der Kolk, of Utrecht, as representing the

committees of their respective countries; and last, not least, from Professor Buniya, and the sub-committee at Turin; the subscriptions in Sardinia being perhaps larger in proportion to its population than that of any other country. As France is erecting a statue of Jenner in her own capital, the Committee could not expect large pecuniary assistance from that country, but her sympathy with the general cause is significantly marked by the subscription of His Imperial Majesty. Liberal donations have also been received from their Majesties the King of Prussia, and the King of Denmark, and many subscriptions have also been forwarded through other channels than those of the committees. In this country the Committee have relied exclusively on the individual exertions of its members, and having been so fortunate as to obtain the patronage and support of H.R.H. the Prince Consort, the Committee have succeeded in raising a sum sufficient with the aid of the foreign subscriptions to defray the expense of the monument. The statue has, by the permission of Her Most Gracious Majesty, been erected on a most eligible site in Trafalgar-square, and is now placed under the care and guardianship of the British Government. Having brought their labour to a successful termination, the Committee take the opportunity of expressing a hope that while the monument records the universal gratitude so justly due to Dr. Jenner, it may also direct public attention to the importance of vaccination, and lead to the erection of similar memorials to other men of distinguished literary and scientific eminence.

The reading of the Report was received with a loud and unanimous outburst of applause.

Dr. CONOLLY then rose and said:—As chairman of the Committee, I presume to address a few words to your Royal Highness on this occasion; chiefly to express my joy that after long delay, and after many difficulties, the Committee for erecting a statue to Jenner in London, can now have the satisfaction of saying that it is done. (Applause.) Thus with the help of almost every country in the world, they have succeeded in paying some measure of the large debt owing from this nation, and from all the nations of the world, to one of the greatest benefactors of the human race. It will, I trust, be eventually gratifying to all who take just views of the various modes in which good may be done, to behold in a place already adorned with the statues of distinguished commanders who bravely fought and bled, and even gave their lives to secure our homes and our possessions, the addition of this simple statue to a physician who banished from those cherished homes, and from our possessions all over the globe, an enemy more destructive than armies and fleets, and more productive of sickness and pain, and disfigurement and death, than war itself. (Cheers.) What has been done to-day will, it is to be hoped, perpetuate the memory of Jenner, and re-awaken attention to his services, and confirm the unquestionable benefit of the great discovery meditated and perfected by a country doctor, a clergyman's son, in the quiet valleys of Gloucestershire, but for the benefit of all mankind. In all future years it will give rise, let us also hope, to an exalted ambition in many young and aspiring students, and animate them with the Divine wish to do some good to their fellow-men before they themselves grow old and die. (Hear.) Jenner began life with no remarkable advantage of fortune or of education. He was brought up in the country, and received the usual amount of instruction afforded to English boys in the middle of the last century, a routine which continued to prevail long afterwards, and than which nothing could be duller or less inspiring. But there was implanted in him a power of observation, and a strong love of the works of nature; and even before he was nine years of age, a fondness for natural history had strongly displayed itself in his mind. Some seven years of surgical apprenticeship succeeded to his school-days, years chiefly devoted to composing pharmaceutical mixtures, and to taking country rides by night and day in the service of the sick. But all this ordeal passed, Jenner had the great good fortune to be placed, at the age of 21, as a pupil in London in the house of one of the most distinguished of physiologists—in the house of John Hunter—(applause)—a house in which no day passed without some occupation or some observation calculated to animate the mind, to extend knowledge, and to promote truth. (Hear.) The ability he displayed as a pupil of so great a teacher, led, at that time, and afterwards, to offers of appointments promising many advantages. But there was entwined in the

heart of Jenner, with the love of natural science, a deep-seated desire to return to the village in which he had been born, and to observe and worship nature in rural scenes dear to his memory. We can scarcely refuse to assent to the belief of his devout biographer, the late Dr. Baron, that his inclination was as the direction of a Higher Power, for in no other locality than that of the district he so loved,—nowhere but in the meadows and dairies of Gloucestershire could he, perhaps, have become the discoverer of vaccination. The first suggestion of the important fact of which his life was thenceforth devoted to proving the truth, seems to have caught his attention even before he went to London, and when he was but 20 years of age. A young woman had come one day into the surgery at Rodbury; the small-pox happened to be talked about, and the young woman said, "I cannot take that disease, for I have had cow-pock." This expression was never forgotten by Jenner. He mentioned it to his great master John Hunter, when in London, who never discouraged useful inquiries; yet thirty years more passed before Jenner published his first work on "Variolæ Vaccinæ." On quitting London, we find that he cheerfully devoted himself to the life of a country Surgeon. His pursuits in natural history were continued, and would alone have distinguished him; but he was also most assiduous in his Profession, practised it with great success, was esteemed for his skill, and beloved for his humanity. (Applause.) None of the affectations of inferior genius seem to have deformed him; no assumption of superiority, no rudeness of conduct, no seclusion from his country neighbours—he spared no pains to diffuse knowledge among them; of those whom sorrow and pain afflicted he was the tender consoler, and in the cheerful circle of his friends he was the lively partaker and promoter of every honest gaiety. But wherever he was there was one idea ever lying deep among his thoughts—the influence of the cow-pock in preventing small-pox. In this subject he constantly endeavoured to interest others, and although often listened to with sympathy, yet sometimes it must be confessed with impatience. To all reasonable objections Jenner was invariably attentive; and to all instances of failure, and to anomalies of every kind, he devoted his utmost powers of investigation, so as in the end to explain them, and to establish more and more firmly the great truth which was ever in his view. Ten years after its first dawning in his mind he saw history clearing through the various obscurities and contradictions which had so long obstructed it; and riding with his friend, Mr. Gardner, on a day in May—perhaps on his birthday; if so, his thirty-first birthday—he first ventured on a full disclosure of the dearest hope of his heart, yet not concealing his anxiety lest disappointment should await him after all. He had caught a glimpse of the great task he might live to perform; but lingering clouds and shade had not quite passed away from it. It would be tedious to my learned and distinguished audience if I were to attempt to detail, or even to enumerate, the various points which still called for Jenner's careful consideration. The student of medicine may with great profit give his attention to them in the memoirs of Baron and Pettigrew, so as not to be discouraged in the pursuit of truth, although it is still and ever difficult "to climb the steep where Fame's proud temple shines afar." (Applause.) Sixteen laborious years passed after Jenner's communication to Mr. Gardner before the first great experiment was made of vaccinating another person from one casually affected by cow-pox in milking. On the 14th of May, 1796, a healthy boy, named James Phipps, had the matter of cow-pox, taken from the hand of Sarah Holmes, a dairymaid, inserted into his arms by two superficial incisions. He went through the vaccine disease favourably. The great question remained—was the boy safe? On the 1st of July in the same year, James Phipps was carefully inoculated with the matter of small-pox by several incisions, and no small-pox followed. What anxious days and nights must have been passed by Jenner between the inoculation and the great result—who can tell? But it is worthy of remark as characteristic of his sedate and earnest temperament, that now, immediately after this success, which might have made an ordinary mind giddy, when briefly relating what he terms the delightful part of his story he adds, "I shall now pursue my experiments with redoubled ardour." With this first successful vaccination began a series of events surpassing fable. A mortal man had been permitted to stay a wasting pestilence. On reading the subsequent steps of Jenner's progress through many long years—his further successes, the difficulties patiently over-

come, the honourable and cordial reception given to his discovery at home and abroad—the feeling left in the mind, and which seems ever to have been in the mind of Jenner, is that of profound gratitude to the Giver of all good, who allows the creatures of His hand to be elevated into the instruments and dispensers of His blessings. (Applause.) If I did not fear to trespass on your Royal Highness's time and attention too long, I could dwell with pleasure and with truth on the generosity as well as on the genius of the artist whose graceful statue of Jenner we are assembled to inaugurate, and on the untiring zeal and labour of the honorary secretary for the advancement of the object of the committee now after many years effected. (Renewed applause.) One circumstance more I cannot silently pass over: of those distinguished persons who more than half-a-century ago were among the first to acknowledge the merits of Dr. Jenner, few remain alive; but we have the singular happiness as well as honour of seeing here this day a nobleman who presided at a meeting of the friends of Jenner in 1805, and powerfully advocated his claims in Parliament in 1807, and whose patronage of art, science and literature, and his many virtues, have long made the name of Lansdowne one of which the English are most proud. (Loud applause.) I rejoice that at least this illustrious person has lived to see that we are not altogether forgetful of Jenner. Among our grateful and glad feelings in connexion with the name of Jenner, we never forget that the discovery of vaccination has immeasurably contributed to preserve the health and strength and beauty of the sons and daughters of England, and to enrich the domains of our beloved Queen with women who adorn, and men who can defend, a country which arts and sciences and liberal institutions make worthy of being defended. (Applause.)

Dr. SEATON, then rising, said, It has been thought desirable by the Committee for erecting a statue to Jenner, that a short statement should be submitted to your Royal Highness and to this meeting, illustrative of the great benefits conferred upon mankind by this discovery. There are comparatively few now living, whose recollection can carry them back to the end of the last century when small-pox continued to be, what the most eloquent of modern historians describes it as having been a century earlier, the most terrible of all the monsters of death. "The havoc of the plague," he says, speaking of the death from small-pox of Mary, wife of William III., "the havoc of the plague had been far more rapid, but the plague had visited our shores only once or twice within living memory, but the small-pox was always present, filling the churchyards with corpses, leaving on those whose lives it spared the hideous traces of its power—turning the babe into a changeling, at which the mother shuddered; and making the eyes and cheeks of the betrothed maiden objects of horror to the lover." The ravages, indeed, which this disease made sixty years ago, were even more severe than those of the period of which the historian writes, for the practice of inoculation of the small-pox, introduced in the meanwhile, though it procured for individuals who submitted to it (not, however, without some risk of life) immunity from any further attack of the disease, had the counterbalancing disadvantage of perpetually keeping alive the source of infection. It was the calculation of Dr. Heberden, that in consequence of this there occurred in London at the close of last century, five deaths from small-pox for every four which there had been at the commencement of it. One-tenth, indeed, of the entire mortality of this metropolis is said to have been due to this disease; and it was computed, that of every million of persons living in England, 3000 perished from it every year. Then it was that Jenner made known that he had discovered and matured a process whereby, without risk to themselves, without the possibility of doing harm to others, mankind might be secured against this pestilence as completely as they were known to be secured when they had already passed through an attack of the natural or inoculated disease; and it was evident that if this representation should turn out to be correct, the ultimate result to be expected from the universal adoption of this process would be the extermination of this frightful scourge. No wonder that a discovery which promised so much should have been received with enthusiasm by some, with distrust by others. It was eagerly subjected to experiments and inquiry. It speedily received the sanction of the highest Medical authorities, and became an established practice at home and abroad. Within a few years of its promulgation,

it was submitted by Parliament to the Secretary of the Royal College of Physicians, and upon their most favourable report the foremost members of the House of Commons of that day vied with each other in honouring the great benefactor of mankind. Fifty years more of observation have but served to confirm the opinions expressed by the College, and to extend the practice of vaccination. Its universal performance in early life is recommended now by the whole Medical profession with an unanimity unknown in almost any other point of Medical or hygienic practice. And there is scarcely to be found an educated man in civilized Europe who does not consider the vaccination of his children to be as much his duty as the providing them with clothing or with food. The effect of this discovery was soon felt throughout the world. There is no civilized nation which has not every year to count up its thousands reserved from death and hideous deformity by this priceless boon. In exact proportion to the extent to which it has been adopted, and the care with which it has been performed, has small-pox, in its fatal and disfiguring form, receded before it. Once this disease constituted a tenth of the whole mortality of this metropolis, now it does not greatly exceed one hundredth. Did it prevail in England and Wales at this present day, as it did at the close of the last century, we should be losing from it more than 55,000 persons every year; whereas the annual average of the last eight years—from 1848 to 1855—for which the death records are accessible, scarcely amounts to 5000. In this division of the kingdom alone there is an annual saving of 50,000 lives; and if our calculation were extended over the world, and through the entire period which has elapsed since the discovery was offered to mankind, its saving influence would be found to have been felt by millions.

Sir JAMES CLARK, Bart., next rose, observing—The Committee, your Royal Highness, have assigned to me the pleasing duty of returning thanks to foreign nations for the support they have given to this movement, and I beg, accordingly, to move, "That this meeting recognises, with a deep sense of admiration, the enlightened and generous spirit in which foreign nations have sympathised with England in their estimation of the benefits conferred on mankind by the discovery of vaccination, and hereby tenders to them its cordial thanks for their liberal contributions to the fund for erecting a statue to the memory of Jenner." (Applause.)

Dr. HAWKINS seconded the motion, which was put, and carried at once with acclamations.

The MARQUIS OF LANSDOWNE then said—Before moving the resolution I now hold in my hand, your Royal Highness, I feel sure that it will meet with the warm concurrence of all present, and be carried at once amid acclamation, I must apologize for my position here, surrounded as I am by men of so much superior talent; and I am bound to explain my presence here to-day, from the fact that I have actually been invited to be present on what may be called a festive occasion, for it brings back to life the services of one of the most eminent men that ever lived. (Applause.) Here a layman and an unlearned person—while the most able and learned could not form a judgment on the subject—was the means, by his indefatigable studies, to complete one of the greatest discoveries ever made. (Hear, hear.) To an accidental circumstance, your Royal Highness, when a member of the House of Commons, I had the pleasure of proposing a motion, to confer on the great discoverer of vaccination an ample, but not more than an ample reward for his important services to the State; and I experienced on that occasion, which I always did in the House of Commons, and in the representatives of this country, a ready disposition to acknowledge superior merit when superior merit is laid before them, and a readiness to open the public purse to reward that which the public considered as worthy of being rewarded. My experience in the House of Commons led me to have some intercourse with that eminent person Jenner, both in town and country. Objections were made to his scheme, but this was generally only amongst the vulgar classes; among the higher classes there was a willingness to admit the merit of the great discovery. Every opposition was tried for a long time; the opponents tried to throw ridicule on it; then it was made a religious question with some; and then some tried to argue that the effect of vaccination would be to injure the human understanding by mixing it with that of animals. (A laugh.) The opposition was met by great perseverance on the

part of the great discoverer himself, and he was enabled at length to bring the voice of the country to bear with him, so that he received in his latter days that reward from the public he so richly merited; and now as a last mark of public estimation, we are assembled in this room, with His Royal Highness at our head, to do honour to Jenner.

Dr. MAYO seconded the resolution, which was carried amidst loud applause, the whole assemblage at the same time rising.

PRINCE ALBERT replied: As the resolution just passed concerns myself, I beg to return you my best thanks, and I trust that the result of this meeting may be to awaken and arouse attention to the merits of the great discoverer of vaccination, and that it may be the means of preventing that neglect of vaccination, which I am sorry to say calls for no less than 5000 victims in this country annually. I beg once more to return you my thanks for the honour you have done me. His Royal Highness then retired, and the proceedings terminated.

## MEDICAL REFORM.

### DEPUTATION TO THE SECRETARY OF STATE FOR THE HOME DEPARTMENT.

On Saturday last a numerous deputation of Medical men waited upon the Right Hon. Spencer Walpole, Secretary of State for the Home Department, for the purpose of enlisting his support and that of the Government to the Medical Bill introduced by the Hon. W. Cowper, M.P. Mr. Adderley, M.P., President of the Board of Health, and Mr. Sotherton Estcourt, M.P., President of the Poor-law Board, were in attendance with Mr. Walpole.

The deputation consisted of Sir Charles Hastings, M.D., President of the Council of the British Medical Association, of members of the Medical Reform Committee, and Secretaries to various branches; Professor J. Hughes Bennett, M.D., Edinburgh; Dr. C. H. Lect, Secretary to the Apothecaries' Hall of Ireland. The deputation having been introduced,—

SIR CHARLES HASTINGS said, that as representatives of the British Medical Association, they had agreed upon certain principles as to the basis on which any Bill for improving the condition of the Profession should be framed. These were—registration of all duly-qualified practitioners, uniformity of qualification, as far as practicable, equal right to practise, and the establishment of the representative principle in governing bodies. The right hon. the member for Hertford, acting on behalf of the late Government, undertook to form a Bill with the view of carrying out those sound principles of Medical legislation for which the British Medical Association has ever contended. That Bill has been introduced into the House of Commons, and stands for a second reading on the 2nd of June.—“As a Committee of the Association which we represent, it has been our duty to examine that Bill carefully, and we have come to a deliberate conviction that it is worthy of our best support. We do not assert that it is a perfect measure, but we are convinced that the Bill is calculated to remove many of the evils that have been so long felt by the public as well as by the Profession. We have ventured to suggest certain alterations to Mr. Cowper, to which he has kindly consented to give his best attention. We come, therefore, to you to give the sanction of your high name and station to this Bill, and to prevail upon the Government, of which you form a part, to lend their aid in passing it into law. Believing, as we do, that any Government will deserve well of the country which, by improving Medical education, shall ensure, in times to come, that sanitary laws shall be more generally obeyed, for then much of the misery which now oppresses a large portion of the community may be mitigated, and health and happiness more generally prevail; and we may here, perhaps, without impropriety, remark that, as an independent body, having no corporate interests or vested rights to defend, we may be fairly presumed to take an impartial view of the Bill.”

MR. WALPOLE: You say you have made some suggestions to Mr. Cowper, and that he has accepted them. Will you tell me what those suggestions are?

SIR CHARLES HASTINGS said, they were in reference to the standard of education which should be required by medical

practitioners. It was most desirable—whether they had one or more councils of examination—that they should have a law which should come up to a certain standard of education. In the present instance there were no less than twenty-one bodies which had the power to pass medical men, so as to enable them to practise, and each of them adopted a different basis or standard of education, the result of which was that only half-educated medical men, in accordance with some standards, got into practice; and they felt that there should be one council and one standard of education, and that the very highest that could be obtained before the candidate should be permitted to pass. Another suggestion was that they thought it most undesirable to keep up the distinction of apothecary.

MR. SOUTHAM, of Manchester, said the committee of the British Medical Association were of opinion that the three distinctive appellations should be abolished, and that there should for the future only be two, namely, that of physician and surgeon.

Dr. BURN, of Bristol, said it seemed to them, in the first place, that it would be desirable that there should be a central council, which should not only fix the standard of education for medical practitioners, but that they should also have the power to enforce it—without that the powers of such a council would be useless. It would be no use whatever to give power to a council to draw up a scheme to regulate the standard of education required for medical men, unless they had also the power given them to ratify or refuse to ratify their credentials, which credentials should be the only guarantee to the public that the person holding them was a duly qualified medical practitioner. He (Dr. Budd) believed he was speaking the sentiments of the entire deputation, when he said that they looked upon the point as the very essence of a measure calculated to benefit the profession and the public, and that they would rather not have the bill at all if this power were withdrawn. (“Hear, hear,” from the deputation.)

Dr. LANKESTER said, the great point they had in view was to get rid of a third person in the medical profession, known as a General Practitioner. In all the large cities and towns of the kingdom a general practitioner was a Surgeon, and what they wanted to do was to let there be but two classes in the profession—Physicians and Surgeons. It was in their opinion unwise in legislation to keep up these professional distinctions. The College of Surgeons, for the last 25 years, had compelled an examination, only applying to particular branches of the medical science; but what they contended for was, that every one taking the position of a Surgeon, ought to have the same education as a Physician; not merely to be enabled to understand the science of anatomy, but that he should have a thorough knowledge of all the branches of the healing art. (Hear.)

Dr. GEORGE WEBSTER, of Dulwich, thought the term apothecary should be abolished in connexion with Surgeon, and that there should only be two classes, Physician and Surgeon, and above all, the necessity for a licence from the Apothecaries' Company ought to be at once abolished. That licence from the Apothecaries' Company was a licence from a mere trading society, and had tended to throw upon the professors of the healing art a great deal of obloquy. There was also a great reform required in the abolition of the term general practitioner. The College of Surgeons gave a diploma for examinations in anatomy, surgery, and physiology; latterly they had added midwifery (the examination in midwifery was not necessary to be a member of the College; it was only an additional means of obtaining increased funds); but those examinations alone were an exceedingly low standard of education for a properly qualified Medical man. It was very different in Edinburgh and Dublin. There, proficiency in the whole range of Medical science was insisted upon, and the result was that Medical men, who had been educated and passed in those schools, possessed a higher standard of Medical education than was obtained in England, on account of the foolish prejudices of the College of Surgeons. He would contend that the necessity for a licence from the Apothecaries' Company should be abolished altogether, although it must be admitted that as far as the Company's examiners went they discharged their duty well. They did not look upon this bill of Mr. Cowper's as a perfect Bill—it was a compromise; but although it was not so good a Bill as they could any of them draw up themselves, still this was the thin end of the wedge, and might lead to something better.

The Hon. Mr. GOWPER said, what he understood the Depu-

tation wanted to bring under the notice of the Secretary of State was, that there should only be two distinctive marks in the Profession, namely, that of Physician and Surgeon. At present, a member of the College of Physicians was prohibited from practising surgery; and to so great an extent was the etiquette of the Profession pursued, that there was a fact on record, that Sir Henry Hallford, whilst travelling in a railway carriage with a personal friend (the late Mr. Lockley), who was seized with apoplexy, and died for want of immediate bleeding, refused to bleed him, because it was contrary to the etiquette of a member of the College of Physicians to do so. (Hear, hear.) [Dr. Webster: He could not do it.] Now, it was a principle of his Bill that, for the future, a Physician should be versed in surgery as well as medicine, and *vice versa*. It was true, a Surgeon might write a prescription now as well as a Physician; but then the Surgeon must write his name in full, whereas the Physician had the privilege of writing a prescription, and simply putting his initials thereto. (Laughter.) That was the distinction. With regard to his (Mr. Cowper's) Bill, he did not repeal the Act of Henry the Eighth, or in any way interfere with the charter to the College of Physicians. Therefore there is nothing calculated to interfere with the dignity of the College of Physicians. The object of the Bill was to insist on the highest standard of education as a qualification to persons to practise medicine and surgery throughout the kingdom, and that that standard should be fixed by a council or body appointed for that purpose, and that there should be one standard of qualification instead of several. At the present time there was great difficulty in defining what is a Physician, in consequence of the conflicting claims of the Universities of Oxford, Cambridge, and London, each of which maintained the right to confer degrees as Physicians, each adopting its own standard of qualification. Therefore, in proposing to fix the standard of qualification in the way described by his (Mr. Cowper's) Bill, he did not see that the College of Physicians could in any point complain, as he left them just where they were. It did not interfere with them as Mr. Headlam's Bill did, but left them just where they were, so far as their rights and privileges as Physicians were concerned.

MR. WALPOLE: "I have paid much attention to this subject, and I think, in the first place, it is exceedingly desirable that there should be no exclusive practice within any particular limits; secondly, I agree that it will be exceedingly desirable that the Medical Profession should get a proper registration, so that the country might know who were duly-qualified Medical practitioners. In the third place, it seems necessary that the public should have a guarantee from some council as to the qualification of every practitioner. In all this I go with the deputation." Then came the question as to the licensing power to be kept up by the several Medical bodies now existing. If they were to commence to legislate *de novo* upon this subject, then it would possibly be advisable that the power of licensing should be in one central body, but he thought wherever it was otherwise it was advisable to legislate, so as to make charges as small as possible compatible with the public interest. His fear was, whether Mr. Cowper's Bill kept up proper distinctions between the various classes of the Medical Profession. The objections raised were, that if they gave all the power to a central council sitting in London it would have the effect of preventing the participation of duly and highly-qualified Medical practitioners throughout the country attending it, and the result would be that there would not be so many eminently qualified Medical men in the country as there were at present. Again, it was urged that the effect of having but one council sitting in London, which was to be the only medium through which a legal medical qualification could be obtained, would have the effect of destroying the competition which now existed in the various schools of medicine, and would thereby not get the best Medical practitioners to come up to town, but they would depute others. He (Mr. Walpole) was of opinion that if they could keep up the existing corporate bodies in conjunction with a council, the effect would be to send out throughout the country the best practitioners. There were four bills now before Parliament upon this very important subject, and what he proposed to do was this—to get the whole of those bills and see what was the best measure he could frame from them. He admitted that the principles enumerated by the deputation ought to be embodied, namely, the right of the public to a

guarantee as to the qualification of Medical practitioners, by means of registration, at the same time to maintain the rights and privileges of different existing Medical institutions. These were his opinions at the present time, but he did not wish it to be understood or to go forth that he was to be bound by them after further investigation of the subject. These were the objects he had in view, and he thought if they were carried out they would meet all the requirements of the Medical profession and the public.

The deputation having thanked the Home Secretary for his courtesy, then retired.

## MEDICAL ETHICS AND MODERN THERAPEUTICS.

We recommend the following portions of Dr. Sieveking's introductory lecture to his course of *Materia Medica*, to the special attention of our readers:—

"The greatest safeguard against quackery is the unity and uprightness of our own body. The proverbial dogmatism and opinionativeness of the medical man lowers him more than a confession of inability to solve questions that are beyond his reach. Few of the facts of therapeutics are capable of mathematical demonstration, therefore I repeat that, with the most intense zeal for science and the warmest devotion to the practical execution of your professional duties, you will consult your interests best by always bearing in mind your own liability to error, and by avoiding harsh and overweening judgments upon your professional brethren. While, however, warning you against an undue confidence in your own views, I have no desire to inculcate scepticism. The sceptical physician cannot but expect to find his patient devoid of faith—a state of things even more unsatisfactory than superstitious delusions on either side. How, then, are these two shoals to be avoided? By a conscientious acquisition of real knowledge, by rigid truthfulness on the one hand; by the avoidance of supercilious assumption or assertion, and of a familiar discussion of your proceedings with your patient, on the other. It is impossible for me to lay down a line of conduct which will apply to every individual case. You must be your own judges; but with the highest aim before you, guided by the rule, 'to do unto others as you would be done by,' you are not likely to err far. I cannot dismiss the subject of ethics yet. It is one of so much consequence in your relation to your patients, it will have so much influence upon your future social position, and it bears so close a relation to the subject I have undertaken to teach you, that I beg of you to listen to the few remarks I shall yet make, connected with this matter, with attention. I shall only be able cursorily to indicate the points which deserve your consideration.

"The relation of the medical man to his patient is one of peculiar intimacy. The former is more frequently made the depository of secrets of the individual and his family, than any other man. And at all times he has more opportunity of seeing the human heart bared, stripped of all conventional tinsel and disguise, than falls to the lot of the lawyer or even of the clergyman. The patient necessarily inclines to open his inmost thoughts to his physician; he himself feels the relation of his physical and mental acts, and he naturally expects the physician to appreciate that relation. The first condition then, is, that the medical man regards all professional communications as strictly confidential and sacred. Let all your acts proceed from a real interest in your patient, and he will be certain to feel that confidence without which your labour will not be blessed.

"One touch of Nature makes the whole world 'kin.'

"There is no need of a difference of behaviour to the poor and the uneducated, or to the wealthy and educated. In manners they may differ, but depend upon it, that upon none will real delicacy of thought and feeling be wasted. Your position gives you a privilege of speaking of, and entering into subjects of the most delicate character; in no case do so unnecessarily; in no case avoid it when the welfare of your patient demands it, from apurrious modesty. Uprightness of purpose, sincerity of heart, kindness of manner, will engender confidence in you and in your remedies. No scientific acquirements can stand in stead of such qualities; the success with

which the former will be brought to bear, will depend materially upon the gentlemanly and Christian feeling which serves as their basis.

"In no case do these remarks apply more than in your intercourse with children. It is often thought necessary to employ artifice and deception in order to secure their obedience. Nothing is more to be deprecated either in domestic life, or in regard to the Medical man. The child will respect and love you in proportion as you instil into it sentiments of respect and love by your behaviour; and though it may not be able to argue on the subject, it will instinctively attach itself to you, if it learns to feel that what you do is not done capriciously, but lovingly. It is a test of your fitness to be a professional adviser, if children love you though you administer nauseous remedies, or use painful operative measures. Discountenance as much as you can the prevailing tendency of mothers and nurses, to make the Medical man and his prescriptions, a bugbear and a means of punishment. Whether in the child or in the adult, bear in mind that 'the mind diseased' is but too often the result of disordered functions; while, in the adult more especially, and particularly among the higher classes, you cannot too constantly recall to your memory that 'Hope deferred maketh the heart sick, but when the desire cometh it is a tree of life.' In the treatment of disease you must never lose sight of the reciprocal influence of the mind and the body, whether it be the sentiment of love that occupies the mind of the youth or the maiden, the disappointment of ambition that harasses the man, the anxious care for the success of their children, or for the realization of the various hopes and wishes that animate mankind,—the desire of literary or social distinction, the endless phases of the overwrought brain or the anxious heart—all may engender or foster disease—all will influence the action of your remedies, aid or exalt, neutralise or counteract them, according as you correctly appreciate their influence in the individual case before you. Let not this multiplicity of considerations alarm you, it is this close connexion between all the different relations in which human nature presents itself to you, that offers one of the greatest and most enduring charms to the zealous student of Medicine. Approach the study with a devout mind, and it will never fail; like Antæus, you will gather strength from every contact with the soil of your profession; reserved vigour will infuse new zeal, new love, even new reward. . . .

"It is at the bedside that you must each of you learn to appreciate the true value and use of drugs. You will gradually learn to form your own opinions on this important subject. But if anywhere in medicine, it is in this department that no rash conclusions should be formed. It is here that hasty generalization proves particularly dangerous; it is here that you will be especially called upon to cultivate that modesty of judgment which is the main distinction between the man of scientific acquirements and the empiric. For this reason I give you a warning, which doubtless will be given you by your excellent lecturers on the practice of medicine and surgery, not to regard the contents of the Pharmacopœia as the sole means of curing disease at your command. Rest, abstinence, or other dietetic measures; the whole doctrine of hygiene and regimen of body and mind; form as essential a department of *Materia Medica* and *Therapeutics*, as any of the drugs which I shall have occasion to speak to you about. You will avoid one of the dangers most fatal to successful practice, scepticism as to the resources of your art, by duly appreciating all these points. Many of them come more under the province of the lecturer on Physiology, in whose hands I may safely leave them, rather than under my own; still it will be my duty to advert to these topics so far as they deserve consideration in the actual treatment of disease. You will have ample opportunity of studying and estimating their importance as soon as you enter into the practical performance of your duties as medical men. But you will save yourselves much thought and care, if you early learn to understand the wide scope of the curative agents at your command. It is by availing themselves of agents not contained in the Pharmacopœia, that the quack so often secures an idolatrous public. 'Fas est et ab hoste doceri,' we shall not desert the legitimate path of scientific medicine, while we turn ALL the gifts provided for our use by nature, and multiplied or adapted by her handmaidens, Physiology and Chemistry, to account. We render ourselves amenable

to the laws, not certainly of our own country, but of science, honour, and humanity, if we deal in specifics and panaceas. The empiric is our enemy and the enemy of mankind; but though we may learn from him, as you learn by the experience taught by your own errors, do not compromise your dignity or the dignity of your most honourable Profession, by the manner in which you wage war with him,—the best weapons you can employ to combat his prejudicial influence are the cultivation of your own mind, the careful and conscientious study of your profession, the formation of high principles, the strong attachment to the cause of science, and to your Professional brethren. If we secure our own camp by placing it on the loftiest and most impregnable eminence, the public, who are sure to appreciate us if we command their respect, will soon cease to run after the empiric, and will treat him with the contempt that every Charlatan deserves."

## REVIEWS.

*On the Painless Extirpation of Cancerous Growths by Congelation and Caustic; including a Report of the recent use of Prolonged Congelation in the Cancer Wards of the Middlesex Hospital.* By JAMES ARNOTT, M.D. Pp. 28. London. 1858.

In this pamphlet, Dr. Arnott advocates the employment of congelation as a painless method of removing cancerous growths; but as this method alone would probably occupy a very long period in its application, the use of caustic is recommended in addition to the freezing agents. The process by which a cure is effected in such cases is thus explained by Dr. Arnott:—"If a morbid growth is kept in a congealed or frozen state for a very long period by means of a powerful frigorific mixture, it is disorganized or destroyed; and if caustic be applied at the same time, or immediately afterwards, this disorganization is quickened, increased, or completed. The destruction of texture can be limited or controlled with the greatest accuracy, by confining the freezing mixture and the caustic to the part by a broad flat ring, or cup made of gutta-percha, fitted to its surface, and firmly pressed upon or adhering to it." One of the cases treated in this manner by the author at the Middlesex Hospital is described at length, and the treatment appears to have been successful; but the date of the operation is too recent to allow of a judgment being formed of the permanency of the cure. Another case is recorded, but it does not appear to have been watched to its termination.

*Evil Results of Overfeeding Cattle.* A new Inquiry, fully illustrated by Coloured Engravings of the Heart, Lungs, etc., of the Diseased Prize Cattle lately exhibited by the Smithfield Cattle Club, 1857. By FREDERICK JAMES GANT, M.R.C.S.E. Pp. 39. London: 1858.

Mr. Gant has here brought before the notice of the public a very interesting subject in connexion with the modern system of overfeeding cattle for the purpose of competitive exhibition. He has shown that when cattle are fattened in an excessive degree, the fat is not only deposited beneath the skin, and upon and around the muscles and other parts, but an interstitial deposition of fat takes place within the muscles, usurping the place of the muscular fibres, and rendering the animals liable to serious, and often fatal disease. Microscopical illustrations of healthy muscular tissue as contrasted with that affected with fatty degeneration, are given by the pencil of Mr. Lens Aldous, in corroboration of the statements contained in the text; and there are coloured representations of the heart, lungs, and muscular fibres of diseased sheep and oxen, showing the visible alterations effected in these structures by the process of overfattening. The miserable animals subjected to this treatment appear to suffer much during life, and their flesh, after death, is deteriorated as an article of human food. Mr. Gant has rather proposed a subject for further inquiry, than pursued it in all its details; but still the materials which he has collected possess a great importance in the present day, when the highest personages in the land are yearly pursuing

a course with regard to the feeding of animals which is opposed to sound physiological laws, and which does not seem to produce beneficial results of any consequence to counterbalance its obviously injurious tendency.

*The Medical Profession in Great Britain and Ireland, with an account of the Medical Organization of France, Italy, Germany, and America.* By EDWIN LEE, M.D. Part II. British Medical Organization. First Division. London: 1858.

In the present portion of this work, Dr. Lee gives a very unfavourable account of the two Royal Colleges of Physicians and Surgeons in London. While admitting the justice of many of the remarks which are made upon the former and present tactics of these Corporations, we must repeat the remark made in reviewing an earlier portion of Dr. Lee's treatise, that he seems more anxious to exhibit the ancient defects in our Medical institutions than to award them any credit for recent improvements. In the account of the College of Physicians, we are carefully informed of the obnoxious nature of the by-law which once prevented those who were not graduates of Oxford and Cambridge from becoming fellows of the College; but from Dr. Lee's remarks we are hardly able to discover, what is nevertheless well known, that this by-law was repealed long ago. Besides the history of the Colleges of Physicians and Surgeons, there is a short account of the other Medical Institutions and Hospitals of Great Britain and Ireland; but there is little information that may not be gathered from the "Medical Directory," or from our own "Student's Number": and the carelessness with which the materials have been compiled may be collected from the fact, that the University of London is described as being a handsome edifice, situated in an airy part of the metropolis, and possessing rich museums, spacious lecture-rooms, and a Medical school which holds the highest rank among the Medical schools of London. Dr. Lee is evidently unaware that the University of London is located in apartments in Burlington House, Piccadilly, and that it possesses neither lecture-rooms, museums, nor Medical school.

*The Institutes of Medicine.* By MARTIN PAINE, A.M., M.D., LL.D., Professor of the Institutes of Medicine and Materia Medica in the University of the City of New York. Pp. 1095.

Dr. M. Paine is a learned and erudite man. He is well acquainted with the Medical literature of ancient and of modern times. Forty years, he tells us, he has been actively engaged in the practice of his Profession, and seen more of bleeding than any man in the United States has; and we conclude that for many years he has also been an instructor of the rising generation of American Medical students. He writes in the language of a man who is profoundly convinced of the truth of what he teaches, and who feels that his authority should be submitted to without question. Such an author must naturally engage our attention; and a large volume from his hand must necessarily contain a vast amount of useful information. But nevertheless, the book and the author are quite beyond our powers of criticism. We see things in such a vastly different light from Dr. Paine, that we do not feel capable even of judging of the mode of his perception of them. What we call advances in Medicine, Dr. Paine calls retrogressions. What we look upon as useful aids to a knowledge of the Art, he would designate as spurious deceptions. Besides, with him in Medicine all is ultra-conservatism. He long ago settled his credo; and whatever rolling years, as they pass away, may have added to or taken from the edifice of Medicine, affects him not. Writing, in 1857, from 386, Fourth-street, New York, he says in three lines of preface to this the fourth edition of his "Institutes":—"The work, as originally published in 1847, remains without change, as the author has seen no reason to modify any of his doctrines." We should have been rather surprised to meet with such a statement in a book which embraces the whole circle of Medical knowledge, even from the hand of some musty Professor of an antediluvian university; but to hear an inhabitant of the chief city of go-ahead Yankee land speak thus, is astounding.

Under the Institutes of Medicine, Dr. Paine comprises physiology, pathology, and therapeutics. Let us glance at his opinions in these particulars.

"Solidism and vitalism," he says, "will form the basis of these Institutes. If consistent in all their parts, without a violation of facts, it is, *primâ facie*, a proof of their foundation in nature" (p. 1). "It will be my agreeable task," he says, at p. 5, "to expose in these Institutes the fallacies of the prevailing physical doctrines of life and disease." Modern chemistry, as applied to Medicine, he abhors: "chemical and mechanical philosophy are strangers to the philosophy of Medicine" (p. 8). "The language, and ambition, and hope or confidence, and the visionary speculations of the older and recent chemists are identical." "What we read in Fourcroy, we read in the works of Liebig" (p. 9). Men are leaving, he says, "the bulwark of knowledge, to rear up hypotheses upon distortions of nature, which, for their better success, they dignify by the name of 'experimental philosophy.'" "In Medicine there is but one kind of experimental observation, which consists in the simple study of the phenomena of nature."

Dr. Paine, in his "Pathology," has an equal contempt for morbid anatomists. "The Profession has been split into two classes, taking the names of the Hippocratic and the Neuroscopic or Anatomical Schools." A few of the most "eminent of the Neuroscopic School," Louis, Magendie, and Andral, for example, "have exploded inflammation as a disease" (p. 457). Wherever morbid anatomy is in the ascendant, the practice of Medicine is on the decline. "Look," he says, "at the present state of Medicine in the capital of France for a melancholy exemplification of what I now state." No wonder that Dr. Paine should lament over the fact that his young countrymen resort to such a place for knowledge, and return home imbued with Gallic pathology and Gallic therapeutics; and "that a few have been not a little employed in disseminating these corruptions in this stable land of sound Medical philosophy" (p. 460). He is also not a little angry (p. 462) that "Americans go on to decry the efforts of their own Medical scholars, degrade the whole Profession of their own country, and sacrifice their own Medical literature for what is conceded to be the present Medical literature of Great Britain." Still he respects somewhat the mother country; "I revere the ancestor as a fading luminary, of the largest magnitude, whose resplendent light has only passed into other regions to advance the welfare of other worlds."

It would be unfair, however, not to add what Dr. Paine says at p. 463, "In all that I have now said, I may not be suspected of undue partialities, for I am under no obligation to any portion of my Profession in America, or of the American Republic; while I am actuated by the deepest sense of gratitude to some foreign countries that can be inspired in a man of literary habits. To those countries I am the more indebted, as they are always just to my native land, do honour to her scholars, and are the great abodes of learning and philosophy" (p. 463).

Let us now say one word of our author's Therapeutics; and of that prime article especially—of Bleeding. "General bloodletting is the proper mode of depletion, especially after the age of infancy, in all forms of fever, and in all the active inflammations of the internal viscera" (p. 713). And Dr. Paine not only teaches but practises his principles. Dr. Paine, in 1847, was attacked by pneumonia. The first remedy used was bleeding to about two pounds; then ten hours later a second bleeding to twenty-four ounces; twelve hours later again twelve large leeches; the next morning he was again bled to about twenty ounces, telling Dr. Bliss, who objected somewhat to the proceeding, "that he would carry out upon himself the practice which he had inculcated in his writings, and had taught in his class." Nine days after this last bleeding, Dr. Bliss found his patient outside his house "at his usual morning exercise of sawing wood." Besides this, his general health, which had been infirm for a long time antecedently, became subsequently much improved.

We suppose that it would hardly do for us to suggest, that possibly the Doctor had never had pneumonia at all. In favour of large bloodlettings, our author quotes a most formidable array of authorities. He will admit of no change in the type of disease. One of his axioms is, that bleeding, which "is equally safe at all periods of life, is most indispensable, in a general sense, in old age" (p. 777); and he

also tells us, "that the local, and even the general abstraction of blood may be remedial, when inflammation is induced by excessive bloodletting alone."

Bouillaud's ill success in treatment arose not from over-bleeding, but because he was too timid in the taking of blood; "he rarely ventured beyond a pound or two." "I," says Dr. P., "am still apt to think with Botalli, that one hundred thousand men perish from the want of bloodletting, or from its not being timely employed, where one perishes from excessive bleeding, when prescribed by a physician" (p. 776). Elsewhere he informs us, that "too small an abstraction of blood is not an unusual cause of inflammation" (p. 773).

At p. 916, we find that Dr. Paine complains of a scientific larceny committed on himself. "The reader," he says, "will quickly find that much that is claimed by Dr. Marshall Hall, and all that is granted to Dr. Campbell in the foregoing quotation, and, therefore, all that Dr. Allen appropriates to himself abounds in this volume."

We have stated already that a modern critic cannot interfere with this volume. Indeed the doctrines contained in it, being unchanged, are the very doctrines which were many years ago submitted to scrutiny by Dr. Carpenter, and (according to the author) were unfairly handled in the *Medico-Chirurgical Review*. These Institutes, indeed, are founded on the "Medical and Physiological Commentaries;" for, in the thousand pages of the Institutes, the Commentaries are referred to at least a thousand times. Our author has his own opinions about medicine, and his opinions differ from those of most men who now administer the art. It would be unfair to him not to say, that a great deal of what he complains of in chemists and anatomists is perfectly true; for we all know what absurdities people run their heads against when they go building up theories of treatment on dead anatomical facts, and chemical or microscopical developments. But our author's grand error is in taking an enormously one-sided view of things. He thinks it impossible for a man to be an Hippocratic and a Necroscopic scholar. He is wrong. There is no reason, either, why a man should not be a first-rate chemist and an excellent Physician, both at the same time. The abuse of a thing is not the proper use of it; and this is just what, as we think, Dr. Paine does not properly understand.

## PROGRESS OF MEDICAL SCIENCE.

### Selections from Foreign Journals.

#### CASE OF POISONING BY SOAP-LEES.

By Dr. DEUTSCH.

At a soap-boiler's, a man, aged 55, drank by mistake a portion of a glass of soap-lees, which at a specific gravity of 1.33 to 1.36 contained 30 per cent. of caustic potass. It was calculated that the quantity drunk must have contained  $\frac{1}{2}$  oz. of the potass; and, notwithstanding his efforts at preventing the swallowing when he discovered his error, at least a fourth part must have reached the stomach. The author, called to him immediately, found the mucous membrane of the mouth and fauces of a bluish-red colour, easily bleeding on contact, and in places separating in shreds. The man complained of an insupportable burning stretching down from the mouth along the spine to the epigastrium, a continuous urinous taste, stabbing pains in the pharynx, and a sensation of constriction along the course of the œsophagus. He could not swallow, every attempt inducing constriction of the fauces. Choking, and an inclination to vomit, were constantly present, but he never completely vomited. He also suffered from irritation in the larynx, causing constant coughing. With all this there were conjoined cold sweats, excessive pallor of the face, collapsed features, faintness, slight convulsions, hiccough, and a very rapid, small, thread-like pulse. The abdomen was distended, and very tender to the touch. Trials having been made in vain to pour down some vinegar and water, some almond oil was got down at first in small quantities, and then in larger, by means of a syringe. This excited repeated vomiting, discharging bloody shreds of mucous membrane mixed with a little of the contents of the stomach, and causing great pain.

The irritation and constriction of the parts, however, became somewhat relieved, so that vinegar and water could be frequently swallowed. In the course of eight days the inflammation of the mucous membrane of the fauces was entirely subdued by the frequent use of cold water gargles; and the patient was able to take milk, and other mild fluids, with little difficulty. He now went into the country, and was only seen again by the author six weeks afterwards; but he now complained of difficulty in swallowing, referring this to the cardiac region. There was no pain, but only an obstacle which allowed only fluids to pass with difficulty, and a large portion of these were soon rejected by vomiting. He had become weak, and his countenance was expressive of deep-seated suffering. The difficulty of swallowing continued to increase, and he perished at last from inanition twenty-eight weeks after he had swallowed the alkali. In the autopsy excessive emaciation was found to prevail. There was nothing abnormal in the appearance of the fauces and upper part of the œsophagus, the latter first showing itself to be considerably thicker where it turns to the left and front of the aorta in the posterior mediastinum. This thickness continued to increase, so that at the cardia it lay in a roll-like form at the upper part of the stomach, measuring in places two inches in diameter. The interior of the tube had undergone a corresponding infundibular diminution, so that the cardiac aperture would scarcely admit a crowquill. The increase in thickness was entirely confined to the mucous membrane, the folds of which were obliterated, and its epithelium unusually developed, and softened as if macerated. The muscular coat, on the other hand, had well nigh disappeared, some thin pale, scattered, circular fibres only remaining. Neither indurated nor ulcerated spots were observable. The stomach, completely empty, was small, contracted, and bloodless, but free from all organic degeneration.

Cases of poisoning by caustic alkali, Dr. Deutsch observes, have been seldom observed. Orfila only relates one case, in which the far milder article, carbonate of potass, was employed. Sobernheim and Simon relate two cases, taken from English sources, one of which (Charles Bell's *Surg. Obs.* Part I. p. 82) bears some resemblance to the one now related. It is upon the fauces and œsophagus that these poisons must chiefly exert their effects, their repulsive taste preventing large quantities being swallowed. The small quantity, moreover, which may still reach the stomach, becomes greatly neutralized by the acids of the organ, or saponified by any fat it may contain. In the present case no gastro-enteric symptoms appeared, the stomach and intestinal canal being entirely normal.—*Berlin Med. Zeitung*, 1857, No. li.

#### EXCERPTA MINORA.

*Light of the Glow-worm.*—As the results of recent anatomical and experimental investigation, Professor Kölliker comes to the conclusion that the illuminating power of the glow-worm does not depend upon phosphorus deposition, illuminated by the access of oxygen; but that it is produced by a nervous apparatus having some analogy to electrical organs. The light is generated just in proportion as the nerves influence the organ. Whatever stimulates nervous action increases the light, and *vice versa*. The proximate cause of the light may be due to electrical or chemical action, and he believes most probably to the latter. He is about to follow out the subject more completely.—*Wurzburg Verhandl.* Band viii. p. 217.

*Charcoal in Burns.*—A Petersburg surgeon speaks in strong terms of the great advantage which is derived from the application of fresh-burned, powdered charcoal.—*Med. Zeit. Russlands*, No. i.

*The Operation for Resection.*—During a recent discussion in the Belgian Academy of Medicine upon a case of resection of the elbow, M. Seutin took occasion to observe that the inclination of Surgeons for having recourse to resection was very much subsiding; and that, for his own part, once a great partisan of this operation, he now very rarely had recourse to it, finding that by patient care, extending over not merely a few months, but for two or three years, an operation may frequently be averted, and a useful stiff joint secured.—*Bulletin de l'Acad. Belgique*, tom. xvi. p. 278.

*Caustic Charpie.*—The nitrate of silver, when applied in its solid form to wounds, sometimes acts too forcibly, while when used in the fluid form its action is too temporary. M. Riboli dissolves some of the nitrate in a small quantity of water, and

having soaked charpie in the solution allows this to dry. Charpie so prepared exerts a more permanent effect upon ill-conditioned wounds than the ordinary solution, while its strength is just as capable of gradation.—*Bulletin de Thér.* April, p. 379.

*Phlegmasia Dolens in Cancer of the Stomach.*—M. Blachez related an interesting case to the Paris Anatomical Society, in which, with a large cancerous ulceration of the pyloric extremity of the stomach, there was phlebitis of the vena cava inferior, the iliac veins, and the right femoral vein, these veins on the right side being completely obstructed and diminished in size. The changes in them were of old standing, and had been accompanied during life with phlegmasia dolens. M. Poisson insisted upon this coincidence of phlegmasia dolens and cancer of the stomach, observing that phlebitis occurring without obvious cause is often connected with a cachectic affection, especially cancer. By this symptom in one case M. Trousseau was enabled to successfully declare the existence of deep-seated cancer.—*Bulletin de la Soc. Anat.* 2nd series, tome ii. p. 28.

*A new Bursa of the Face.*—M. Verneuil demonstrated to the Paris Anatomical Society a new serous bursa of the face, enveloping the fat of the cheek nearly in the same manner as the tunica vaginalis envelopes the testis. This bursa, which is easier found in fat than in thin subjects, because it is in them more superficially placed, is situated behind the zygomaticus major and Steno's duct. It extends below the external edge of the masseter muscle, and under the arch formed by the malar bone, behind which it becomes united to another serous bursa, in the vicinity of the coronoid process. The two bursæ often communicate with each other, and thence extend as far as the base of the cranium. The buccinator forms the internal limit of the genial bursa, which adheres to its surface. It is easy to see how some of the varieties of cysts of the cheek may have their origin in this serous cavity, and its disposition explains the irregularity and depth of the extension of some of them. The existence of the bursa is easily explained by the great mobility of the mass of fat of the cheek during mastication.—*Ibid.* p. 170.

## PROVINCIAL CORRESPONDENCE.

### IRELAND.

DUBLIN, May 19, 1858.

The last meeting for the session 1857-8 of the Dublin Obstetrical Society, was held at the Rotundo on Wednesday evening, 12th May, Dr. Beatty in the chair. After a very able and practical paper had been read by Dr. Sawyer, Professor of Midwifery to the Royal College of Surgeons, Dr. Churchill, Professor of Midwifery in the King and Queen's College of Physicians, rose to reply to an article on "Obstetric Morality," which appeared in No. 87 (for April, 1858, p. 100) of the *Dublin Review*. The article in question was written to show the immorality of the operation of craniotomy under any circumstances, if the child be alive, and Dr. Churchill expressed his dissent from both the theological and obstetrical reasoning of the author, and stated his belief that the writer is not a Medical man. Dr. Churchill entered fully into the subject in a moral, theological and obstetrical point of view. He showed that hastening the death of a child that cannot be born alive is not murder, as the reviewer has termed it, but that according to the law of morals and to the law of the land, it is justifiable and right. He expressed his own faith in the safety of the child's soul when baptism is impossible, and putting aside the question of when and how the soul is first joined to the body, showed that of children dying *in utero*, nothing whatever is said in Holy Scripture, though the reviewer, who based his reasons upon that sacred authority, deduced from the texts he brought forward, that the souls of such children are "not saved." Dr. Churchill argued that the responsibility of the accoucheur for the life of the child ceases when his power over it fails, but that in the one essential particular, his responsibility for the mother does not cease, but rather augments, because that condition is within his own control. He pointed out that craniotomy is not recommended for any case in which the child can be delivered alive *per vias naturales*, and

that, although the mortality to the mother is very high when assistance is deferred until the death of the child has taken place, it is comparatively small when it is afforded in seasonable time. As to the alternative of the Cæsarean section, Dr. Churchill proved that whatever be its mortality, on the one hand, when deliberately planned and arranged previously, with assistants and all the various appliances necessary; when hurriedly performed on the other, with the patient exhausted by prolonged sufferings, and the operator deprived of the advantages of due preparation, the mortality must inevitably be so fearfully high, while the number of children saved would be so small, that were we prepared, as the reviewer is, to sacrifice so many mothers in our endeavours to save the children, the sum total of lives saved would at the best not be more, but might very probably be much less, than by the operation of craniotomy.

The foregoing is a very faint outline of Dr. Churchill's masterly paper; but as the latter will shortly be published *in extenso*, the sketch I have given may for the present suffice. On the termination of the paper, Professor MacSwiney of the "Catholic University," and Dr. James Brady rose to bear testimony to the very courteous and delicate manner in which Dr. Churchill had treated the theological portion of his subject.

## GENERAL CORRESPONDENCE.

### PROVIDENT MEDICAL ASSOCIATION.

LETTER FROM WILLIAM OGLE, Esq.

[To the Editor of the Medical Times and Gazette.]

SIR,—As Secretary to a Provisional Committee of the Provident Medical Association, I write to ask the assistance of those of your readers who know anything of the working of Medical Institutions—whether Dispensaries or not—which are established on Provident principles. I shall be happy to supply any such persons with a tabular form, which will enable them, with comparatively little trouble, to furnish me with the required information.

The Provident Medical Association has discussed very fully the principles, which have recently been revived in your valuable Journal, and these principles have been generally approved. It is now desirable to obtain information as full as possible of the results, in so far as such principles have been applied, that we may test principle by practice, and profit by the experience of those who have laboured in the same field. The following particulars, as they may be expressed numerically, are readily and conveniently brought under notice in a tabular form:—

1. The age of the Institution.
2. Number of Medical officers; (a.) in ordinary; (b.) consulting.
3. Number of ordinary members on the books.
4. Of new members (inclusive of 5).
5. Of members admitted when sick.
6. Of cases of sickness.
7. Of cases visited at home (exclusive of 8).
8. Of cases of midwifery.
9. Of deaths.

#### Income.

10. Subscriptions, donations; interest of funded property.
11. Payments of ordinary members.

#### Expenditure.

12. Paid to Medical officers.
13. Salaries to House-Surgeon, Dispenser, servants, instruments.
14. Rent, rates, and repairs of house.
15. Drugs and leeches.

These facts, when tabulated, give at a glance valuable information; valuable both as regards the history of each institution in successive years; and by way of comparison of one institution with another.

Thus: 1. The age is *pro tanto* evidence of durability. Thus Coventry P.D. has reached its 26th year.

2. The number of Medical officers is a professional testimony, but this requires further investigation; for we must also note the length of time during which the Medical officers

are found willing to continue their services. A separate table might with advantage be devoted to this important item.

3—8. tell of the popularity of the institution, and furnish other information of great social value. It is of importance to record the number of ordinary members (3) as an entry distinct from (4) the number of new members, for otherwise we might be misled. The number of ordinary members in successive years will give the total increase or decrease of the numbers; but unless we have a separate record of the number of new members, we cannot learn how many members have left the institution, and this might be a fact of great significance.

Again, a separate record of the number of members admitted when sick (5) is very important, for bearing in mind that the aim is to encourage providence; a large entry in time of sickness points to failure in this respect, and may disclose the fact that our institution is little better than a shop for cheap medicine!

The number of cases of sickness as compared with the number on the books, gives information as to the comparative health of the members. It is hardly necessary to observe that cases of sickness do not mean persons attended so many weeks or months and then re-entered. There is no purpose to serve in making it appear that a great many patients have been attended during the year. On the contrary, a progressive diminution in the numbers attended, as compared with the number entitled to assistance, is evidence of moral as well as physical soundness.

The cases visited at home, and the cases of midwifery represent the demand which is made on the Medical officers, and the results obtained, which includes much more than the £ s. d., must bear comparison with this sacrifice.

The number of cases of sickness (6) and of the deaths compared with each other, and with the number of members on the books, gives information not otherwise readily obtained.

The income is divided into that which arises from (10) benevolence, which must have a ? attached to it, if letters of recommendation are allowed to be given by subscribers; and (11) the payments of the ordinary members, which speak of their willingness to help themselves.

The expenditure should also be divided into the different headings indicated, because in some Institutions, such as the one at Barham Downs, the payment to the Medical officers would, without such sub-division, seem unaccountably liberal.

Having mentioned Barham Downs, it is but justice to say that in its rules for the admission of ordinary members it is pre-eminent, as far as I have information, for the care that is taken to prevent abuse of the privileges offered. The cost of drugs and leeches (15) should be separately recorded, because in certain questions, such as the equitable remuneration of the Poor-law Medical officer, the information is valuable.

I enclose a table wherein all these facts may systematically be recorded, and I wish to draw the attention of those to whom is intrusted the duty of drawing up reports, to the fact that their labour in recording such particulars as have been noted is not in vain; that it is of great importance to use the same form year by year; and unless there be special reason to the contrary, that Institutions based on the same principles should record the same facts for the sake of mutual edification.

As these benevolent Institutions are generally worked by gentlemen, lay and Medical, of great zeal as well as benevolence, and as good cannot but ensue to each such Institution from the careful compilation of the facts above referred to, I trust that those gentlemen who have it in their power will apply to me without delay for a printed form, and will send me the particulars respecting their own Institution, which can be gathered from the published reports.

I am, &c.

WILLIAM OGLE.

9, Lower Belgrave-street, S.W.

## THE CONSTANT GALVANIC CURRENT.

LETTER FROM MR. H. W. LOBB.

[To the Editor of the Medical Times and Gazette.]

SIR,—In your last week's impression there is a letter from Dr. Althaus, in which he calls in question the beneficial effects of the "Constant Galvanic Current" in the hands of M. Remak of Berlin, in the treatment of rheumatism, hemi-

plegia, atrophy, chorea, etc., quoting some cases in which M. Remak failed to relieve confirmed paralysis. But, because M. Remak failed to cure paralysis with the constant current, that is no reason why he might not succeed with rheumatism, chorea, etc.; in fact, that is the very reason why he should, as they are antagonistic affections.

Now, I know nothing of M. Remak's success with the continuous current; but I know what it has done in my hands, and I believe that the continuous current will eventually be found more useful and manageable than the induced current.

Both are valuable, but in different cases. The Induced in paralysis, and as an excitant generally; the Continuous in neuralgias, rheumatism, cramps, chorea, and, in fact, in all hyperaesthesiae.

I am, &c.

HARRY WM. LOBB.

63, Gloucester-terrace, Hyde-park,  
May 17th, 1858.

## IMPULSE OF THE HEART DURING DIASTOLE?

LETTER FROM ROBERT CARTWRIGHT, M.D.

[To the Editor of the Medical Times and Gazette.]

SIR,—In my letter, January 2, I suggested that in Mr. Groux's case the impulse produced by the base of the right ventricle would immediately precede the second sound; and on the 25th March I went to Manchester and saw Mr. Groux. My arrangements allowed me only a very short interview; but on examination I found that the tumour "a" was evidently the right auricle, and on placing the thumb just below this swelling, under the edge of the sternum, the impulse of the base of the right ventricle immediately preceded the second sound; I therefore consider his case corroborates my views; it should also be stated, Mr. Groux is himself a firm believer in the diastolic theory, and says, "the heart sucks the blood in."

It is surely a deep disgrace to the Medical profession, that after thirty years' discussions, experiments, &c., all that is really known about the action of the heart amounts to the wonderful fact, that the heart either ascends or else descends during its contraction; but the funniest fact of all is, that strictly speaking, it neither ascends nor descends.

In a former letter I mentioned having seen in 1851 a case of stricture of the mitral valve, in which the radial pulse and impulse were synchronous. Dr. Peacock reports, that in dilatation of the mitral valve, there is a greater interval than usual between the radial pulse and impulse; now these variations of the pulse are easily explained by the diastolic theory, but are in my opinion quite inexplicable according to the systolic theory. It might, perhaps, be advanced in Dr. Peacock's cases, that the enlargement of the heart causes the impulse to be felt sooner than usual, but this is not a satisfactory answer, for I have seen two cases, in the one there was the usual interval and no dilatation; in the other there was the greater interval and the dilatation.

It is received as an established fact in Germany, that the impulse is synchronous with the carotid pulse; this objection was made to me by the Assistant-Physicians at the Würzburg Hospital, in Dec. 1851: the objection appeared fatal to the diastolic theory, and made me feel extremely anxious and depressed; for here were two facts apparently irreconcilable, the synchronism of the impulse with the carotid pulse, and the impulse occurring during the diastole, of which fact I was certain from experiments on rabbits. However, after a restless night, on the following morning the happy thought struck me, that the pulse-wave did not pass instantaneously, but occupied exactly the period of one whole beat in passing through the arterial system, (say) from the heart to the ankle. Now the synchronism of the impulse and carotid pulse is readily explained by this hypothesis; but the common explanation, that the carotid pulse appears to be synchronous with the impulse, because it is so near the heart, is not satisfactory; for the carotid must be synchronous with the axillary pulse; and taking it as the representative of the latter, there ought consequently to be, as far as distance explains the fact, no perceptible interval between the carotid and radial pulse.

In 1853, I pointed out to Dr. Alison, at the Edinburgh

Infirmary, a case where the radial artery distinctly preceded the pulsation at Poupart's ligament, and that such was the normal state; he replied, it might be so, but he was not aware of it. Dr. Chaumont, a member of the Physiological Society, corroborated my observation, saying, that he had lately read an article on the pulse, containing a similar statement, but he could not remember the author's name.

Furthermore, I can assure Dr. Halford, that his vivisections were not more carefully or accurately performed, than what I made for the Physiological Society in Edinburgh, in the winter 1853-4. I failed in showing the beautiful and harmonious action of the heart, because the dogs were over-chloroformed; and Dr. H. failed from the same cause; or perhaps the chest was not opened with sufficient rapidity, since the active dilatation of the apex ceases almost immediately, and all the artificial respiration in the world will not re-excite it.

I therefore beg to call the attention of the Profession, and particularly of the Clinical Lecturers, to the following points:—

1. The carotid pulse is synchronous with the impulse.
2. The radial pulse follows the impulse.
3. The radial pulse precedes the pulsation at Poupart's ligament.
4. In stricture of the mitral valve, the interval between the radial pulse and impulse is less than usual.
5. In dilatation, the interval is greater than usual.

In conclusion, allow me to observe, if Physiologists and Clinical Lecturers will mark, learn, and inwardly digest the above five points, the truth will gradually dawn on their minds; for it is utterly impossible that the mitral valve can, according to the systolic theory, have anything whatever to do with the variations of the radial pulse and impulse.

I am, &c.

ROBERT CARTWRIGHT, M.D.

#### PLACENTA PRÆVIA.

LETTER BY E. D. BYRNE, ESQ.

[To the Editor of the Medical Times and Gazette.]

SIR,—I send you an account of a case of Placenta Prævia, which occurred in my practice this week, and I think from the success which attended the treatment will be read with interest by some of your readers, more especially as I do not find it recommended by obstetric writers, so far as I have consulted them, and I shall be glad to learn the opinion, through your valuable Journal, as to the treatment of the case, had it terminated fatally. I first saw my patient, Mrs. S., in the morning, and found I had been summoned on account of severe floodings she had had within the last three weeks. Upon inquiry I found she had borne some eight children, and never had such symptoms before, but recovered well. I had no prior knowledge of her whatever. She stated that the last flooding took place the day before she sent for me, when, for the first time, she was alarmed from the quantity, etc.; at the same time she experienced no pain, and as I found her in bed and expecting daily, I recommended absolute rest, cold drinks and nourishment, and gave a mixture of acid. sulph. dil., magnes. sulphat., and inf. rose, to be taken thrice a day, and left strict orders that I was to be sent for immediately labour commenced. About 10½ p.m. I was sent for, and on arrival found my patient walking about, with slight continued pain and no flooding. Upon examination per vaginam, I found the uterus dilated and soft, flabby, and in the os a soft mass through which the liquor amnii could be felt. At 1 a.m., as she appeared to be growing weaker without any increase of pain, I administered a dose of ergot, viz., ʒj of the powder infused; this took very little effect, and at 2½ a.m. flooding came on, when I introduced my hand and succeeded in rupturing the membranes. The quantity of liquor was very great, much more than ordinary; shortly afterwards, a stronger pain than she had yet experienced forced the placenta into the vagina; immediately after a gush of blood sent it into the world, and from that time my patient lay in a quite unconscious and half-fainting state, and flooding more or less, with a total cessation of all pain. At 3 a.m. I introduced my hand, intending to try and bring down the child's feet, but did not succeed in reaching them, owing to the difficulty of

getting my hand into the uterus. I then gave her a second dose of ergot, viz. ʒas, but it struck me if I could succeed in producing contraction of the womb by direct stimulation, I might save my patient yet; in the meantime I had sent a messenger to Gateshead for my friend, Dr. Barkus, to bring the instruments, as I thought it advisable to deliver as speedily as possible under the circumstances, and being, as I was, three miles from home or medical assistance, and without an instrument, I was very much afraid I should lose my patient before the necessary aid arrived; at this juncture she was lying speechless, when I called one of her attendants and made her rub her abdomen in the same manner you would knead dough, in a quarter of an hour I got a fresh one to work in the same manner, and at the end of half an hour I had the satisfaction to find I had produced slight uterine action, but still without much, if any, pain; I worked on in this manner for an hour, when I found the head of the child descending most decidedly; this gave me great encouragement, and I still persevered with the rubbing up to 5½ a.m., when the child was born—a large, full-grown male. The uterus contracted kindly, and my patient is so far doing well, and Dr. Barkus arrived but in time to congratulate me on my success. Now I do not know whether to attribute (although I am decidedly inclined to do so) the success of this case to the continued action on the parietes, or the ergot; against the latter I remarked that the moment the women ceased their labours there was a total cessation of all uterine action, and I impute the whole success to the unwearied exertion of the women. On returning home I consulted "Ramsbotham," and find no mention of this mode of treatment, therefore I have troubled you at this length, as it is a simple remedy if (as in this instance) it prove successful in more of these fruitful cases.

I am, &c.

E. D. BYRNE.

Whickham, February 26, 1856.

#### THE ABUSE OF HOSPITALS.

[To the Editor of the Medical Times and Gazette.]

SIR,—In your Journal some very just remarks were made recently by Dr. Ogle, respecting the abuses arising out of the Hospital practice of this great city. I would ask your numerous readers, especially those who intend educating their sons as medical men, what prospects of obtaining anything like a comfortable existence will be open to them? Gaudy chemists' shops at the corner of every street, with windows decorated with showy placards, announcing, "A physician of experience prescribes here daily," etc. etc. Dispensaries got up in every direction by gentlemen hoping to talk themselves into practice, and who go round, hat in hand, to the tradesmen of the district soliciting the honour of their votes should a vacancy occur in the staff, although the surgeons of that staff are going out in the night to attend gratuitously in their confinements the wives of well-to-do mechanics and tradesmen, who could well afford to give a guinea on such occasions: as the agricultural labourers constantly manage to do when they have not more than three children. Hospitals with from five and six hundred out-patients a day, many, no doubt, truly deserving relief, and many, especially the well-dressed class, who arrive in cabs (*vide* the Borough), most undeserving. Eminent men, who ought to know better, setting apart a portion of the morning (although themselves in large and lucrative practice, and also attached to hospitals) for gratuitous practice, and taking the bread out of the mouths of well-educated practitioners, by prescribing for publicans, old-established tradesmen, and mechanics earning good wages. And what will be the result of all this? Talk about medical reform! the reform must come from within—no Act of Parliament can effect it. The consulting men are made by the senior General Practitioner, and in their turn crush the younger ones. Of course it suits the interest of a few to sit two or three hours three times a week at a general hospital or dispensary, seeing from forty to sixty patients per hour (how valuable his diagnosis under such circumstances!); it brings grist to the mill—he gets talked about; but should he not be true to himself and his professional brethren by, so far as he can, refusing his advice to those whom he is satisfied are not in circumstances requiring gratuitous Medical relief? Of

course the evil originates with the persons, "governors" or otherwise, who distribute the letters of admission. Tradesmen find it promotes their trade connexion by distributing letters across their counters to all who ask. The rich nobleman or landowner or merchant, too, often sends a faithful man-servant direct to an hospital for an affection which would frequently be well treated at home, the consequence being that the respectable but poor mechanic, who spurns the workhouse relief, is told on applying for admission, "No beds!"

The evil has arrived at such a pitch that an organisation of some kind must eventuate to meet so great an abuse. Let means be taken, by an association of a few practical men earnest in the cause, who would arrange to meet one lay and one professional member of each of the committee of the ten hospitals in London, and some good of a permanent nature will arise out of it, especially if aided by the powerful pens of the editors of Medical journals.

Trusting this important subject will not be allowed to drop,  
I am, &c. A CONSTANT READER.

March 8, 1858.

P.S.—Can any reader point out in the Inns of Court the establishment where gratuitous legal advice is given to all comers?

### THE CASE OF MR. SYMES.

In our last impression we stated that Mr. Symes had received a communication from the Poor-Law Board requesting him to tender his resignation. The following additional correspondence on this subject has been handed to us for publication:—

"Bridgwater, May 13th, 1858.

"My Lords and Gentlemen,—I have to acknowledge the receipt of your Secretary's letter of the 10th instant, and to inform you that I decline to accede to the request made to me therein, viz. to tender my resignation to the Bridgwater Board of Guardians.

"I feel that by adopting such a course, I should be sacrificing my professional character, be quite unworthy of the sympathy which I have received from public opinion, and be virtually admitting the truth of the charges which have been so unjustly brought against me.

"I am, my Lords and Gentlemen,

"Your obedient Servant,

"To the Poor-Law Board."

"Henry Symes.

"Poor-Law Board, Whitehall, (S.W.)

"17th May, 1858.

"Sir,—I am directed by the Poor-Law Board to acknowledge the receipt of your letter of the 13th instant, in which you state that you decline to tender to the Guardians of the Bridgwater Union your resignation of the office of Medical Officer.

"This intimation leaves the Board no alternative but to remove you from the office which you hold by formal order under the seal of the Board. As, however, the issuing of such an order is attended with the disqualification specified in the statute 4th and 5th William IV., cap. 76, sec. 48, the Board will not issue it until Wednesday next, in order still to afford you sufficient time to send in your resignation if, upon reflection, and under the circumstances, you are desirous of so doing.

"I am, Sir,

"Your obedient servant,

"Courtenay, Secretary.

"To Henry Symes, Esq., Medical Officer, Bridgwater."

"Bridgwater, 18th May, 1858.

"My Lords and Gentlemen,—I have to acknowledge the receipt of your Secretary's letter of yesterday's date, in answer to my communication of the 13th instant, wherein I declined to tender my resignation to the Guardians of the Bridgwater Union.

"In reply, I beg to state that, perfectly regardless of the disqualification specified in the statute you allude to, it is still my intention—with many thanks for the kindness the Board have shown me in proposing not to issue their formal order until Wednesday next—not only to adhere to my former

letter, but to protest against the decision of your honourable Board, the result apparently of the partiality of the Inspectors before whom the various charges preferred against me were heard. I can now only feel it is quite impossible to obtain justice at your hands, and that no other alternative remains but to appeal for what you deny me to a higher tribunal.

"I am, my Lords and Gentlemen,

"Your obedient servant,

"HENRY SYMES."

"To the Poor-Law Board, Whitehall, London."

### EAST INDIA COMPANY EXAMINATION.

QUESTIONS PUT IN THE WRITTEN EXAMINATION OF CANDIDATES FOR THE APPOINTMENT OF ASSISTANT-SURGEON IN THE HON. EAST INDIA COMPANY'S SERVICE, HELD ON THE 10TH AND 11TH INST.

SURGERY.

Monday, May 10, 1858.—2 to 5 o'clock.

MR. STANLEY.

1. Describe the chief consequences to which stricture of the urethra may lead; and state briefly the best modes of treating them.

2. Describe the ordinary progress of a case of psoas abscess; and in the event of death, the most usual appearances found on the autopsy.

3. Necrosis of the last phalanx of a finger often follows a rough puncture in a person in feeble health; describe the appearances of the finger during this disease, and say how you would treat such a case.

4. Describe the usual appearances of the blood and blood-vessels in acute inflammation, as seen in the transparent parts of mammalia and reptiles.

5. In what injuries and diseases of the skull would you think it right to remove bone with the trephine or other instruments?

6. Describe the operation for the removal of the eyeball; and enumerate the principal cases for which you think it advisable.

7. A man, advanced in years, and apparently free from complaint, except that his urine was occasionally tinged with blood, sustained a severe fall; shortly afterwards he experienced a violent desire to pass urine, and his bladder was greatly distended. His efforts at micturition were at first wholly ineffectual, but after repeated straining the impediment gave way, and the urine flowed in a full and uninterrupted stream, as it had always previously done. What was the cause of obstruction in this case?

NATURAL HISTORY, ETC.

Monday, May 10, 1858.—10 to 1.

DR. HOOKER.

Answer five or more of the following Questions.

1. What are the distinctions between minerals and organized beings?

2. How does the root of a woody flowering plant differ from the stem in structure and development?

3. What is meant by the natural system of botany? what are its objects; and upon what principles is it constructed?

4. Describe the formation of the stem in monocotyledonous and dicotyledonous plants.

5. To what classes, divisions, and orders of the vegetable kingdom do the plants producing the following substances belong? what are their scientific names?—calumba, cascarrilla, nutmeg, rhatany, black-pepper, ginger, and sarsaparilla.

6. From what countries do these plants come; in what form do the products arrive; and how would you distinguish good from bad samples of them?

7. What are the botanical characters of the natural orders labiate, rosaceæ, conifereæ, urticæ, and convolvulaceæ?

8. What is coal; by what classes of plants is it supposed to have been formed; and what are the chief products of its combustion?

9. In heating barracks or hospitals, what are the comparative values of coal, coke, hot water in pipes, and hot air in flues?

10. In examining materials for bedding, clothing, etc., how would you distinguish microscopically or otherwise, woollen, linen, cotton, hemp, and silk fabrics?
11. What are the principal points to be attended to in the preparation of vegetable extracts?
12. State the distinguishing characteristics between an insect and a crustacean.
13. Define the different modes in which the respiratory function is performed in the animal kingdom, and give examples.
14. Define the terms sensation, innervation, development, evolution, absorption, natural law.
15. What is sound? what is meant by the propagation, conduction, and dispersion of sound?

## ANATOMY AND PHYSIOLOGY.

Tuesday, May 11, 1858.—10 to 1 o'clock.

MR. BUSK.

1. Describe the parts concerned in the different kinds of inguinal hernia.
2. Describe the vertebral column, its relations and functions. Define a typical vertebra in the terms employed by Professor Owen.
3. Describe the anterior, middle, and posterior mediastina, and the parts contained in them, noting the relative position of those parts.
4. Mention the chief anatomical peculiarities which distinguish the fœtus from the adult.
5. Describe the minute structure and modes of development of bone.
6. Describe the mode in which the absorption of different substances is effected in the stomach and intestines; indicating also the course of the chyle, and the changes it undergoes in its passage to the blood.
7. Indicate the sources of heat in animals, the circumstances by which it is augmented and diminished, and the means by which it is prevented rising beyond a certain point.

## MEDICINE.

Tuesday, May 11, 1858.—2 to 5 p.m.

DR. PARKES.

1. Describe the causes and treatment of the following forms of motor paralysis:—(a) paralysis of the lower extremities; (b) paralysis of both upper extremities, or of some of the muscles of them; (c) paralysis of one or more muscles, or groups of muscles, of the face.
2. Describe a fit of epilepsy, and the distinctions between it and forms of disease resembling it.
3. Enumerate the better known abnormal, chemical, and physical alterations of the blood.
4. What are the chief causes of blocking up of blood-vessels (arteries and veins); and what are the results of blockage of arteries at the base of the brain, of the pulmonary arteries, and of the femoral veins?
5. Describe the morbid anatomy of acute tuberculosis.
6. What are the symptoms, diagnosis, and treatment of acute dysentery, and of tuberculous diarrhoea?
7. Give the symptoms, effects, and treatment of whooping cough.
8. Describe the symptoms and various modes of treatment of displacements of the uterus.
9. What are the effects of habitual excess in the use of alcoholic drinks?

## UNIVERSITY OF ST. ANDREW'S.

## MEDICAL EXAMINATION PAPERS. MAY, 1858.

## First Examination.

## FIRST PART.

Translation of a Latin paragraph into English.  
Give the derivations and primary meanings of the following words:—Ægophony, Biology, Diarrhoea, Gastrodynia, Lithotomy, Orthopnoea, Pleximeter.

## SECOND PART.

N.B.—Those who are not candidates for honours are not expected to answer the questions to which an asterisk is prefixed.

## CHEMISTRY.

1. State the source, mode of extraction, and properties of iodine. Give the test for it. What is the derivation of the name?
2. Enumerate the compounds of mercury used in Medicine; stating their composition, and giving the tests for their presence in solution.
3. Write in formulæ the composition of the following substances: nitre, glauber salt, coal gas, laughing gas, triple phosphate.
- \*4. Enumerate the different urinary calculi; giving such chemical characters and tests as would serve to determine each.

## MATERIA MEDICA.

5. Name the chemical substances which are used as caustics. What are the principal uses of this class of remedies, and how would you be guided in your selection of the appropriate substance?
6. What are the chief uses and ordinary doses of the Pharmacopœial preparations of arsenic, zinc, and lead?
7. What are the antidotes to be employed in cases of poisoning with oxalic acid, corrosive sublimate, and sugar of lead?
8. What are the principal varieties of aloes, and how would you distinguish one from another? Compare the purgative action of aloes with that of rhubarb, senna, and jalap.
- \*9. What alkaloids are yielded by the solanaceæ employed in Medicine? State briefly their chemical characters and their physiological action.
10. Write a Latin prescription (without using abbreviations or symbols) for a draft suitable for a case of tape-worm; also for an anodyne draught or mixture suitable for a case of impacted biliary calculus.

## Second Examination.

## ANATOMY AND PHYSIOLOGY.

1. Describe the muscles which take their origin from the inner condyle of the humerus.
2. How is the cervical plexus formed? Describe the principal branches of this plexus.
3. Describe the articulation of the lower jaw and the movements of Mastication.
4. What is supposed to be the function of the pancreas?
- \*5. Give a sketch of the anatomy and functions of the sympathetic nerve.

## Third Examination.

N.B. In answering the practical questions, the examiners require every candidate to specify the mode of treatment which he is in the habit of adopting, and the doses of the medicines which he prescribes.

## PATHOLOGY AND PRACTICE OF PHYSIC.

1. In what diseases do we find the red corpuscles and the fibrin of the blood deviating from the normal standard? What is generally the proper treatment when the corpuscles are diminished in number?
2. Describe the symptoms and treatment of chronic gastritis.
3. Describe the progress of the physical signs in a case of rheumatic pericarditis going on to adhesion, and state what treatment you would adopt.
4. With what diseases is hæmatemesis commonly associated, and what are the chief means of checking it?
- \*5. What are the pustular diseases of the skin? Describe the symptoms and treatment of any two of them. Are any skin diseases supposed to originate in vegetable cryptogamic growths? State what you know on this subject.

## Fourth Examination.

## SURGERY.

1. Give an account of what is known respecting the hereditary transmission of syphilis from either parent; state the

effects produced by syphilis on the fœtus; and the symptoms and treatment of the disease in the infant.

\*2. Under what circumstances is it requisite to make an artificial pupil; and what modes of operation are suitable to the various cases?

3. Describe the process of reparation in a fractured bone.

#### MIDWIFERY.

4. What are the various causes of "lingering labour," and what the mode of management appropriate for each?

5. In what circumstances is ergot of rye useful, and what are the precautions necessary in administering it?

6. What are the symptoms of retroversion of the uterus in the pregnant and in the unimpregnated state, and how is the accident to be treated?

#### Fifth Examination.

##### CASES.

1. In a case of heart disease there are increased percussion-dulness, and diffused pulsation in epigastrium, together with a weak and small pulse, and a strongly-marked second sound over the left border of the sternum, about the level of the third and fourth costal cartilages. There is a loud murmur with the first sound of the heart, distinct below the nipple, indistinct at base, inaudible in the neck. The veins of the neck are turgid in coughing, and pulsate slightly. The point where the apex beats cannot be ascertained.

With these signs are associated dyspnoea, hæmoptysis, dulness on percussion in the right back over the base of the lung, crepitating râle, and some degree of tubular respiration. The urine is scanty, high coloured, of high density, faintly albuminous. There is dropsy of the feet and abdomen; the liver is enlarged; and there is slight jaundice.

You are requested to discuss in writing:

(1) The probable state of all the organs and functions mentioned above.

(2) The probable order of occurrence of the morbid phenomena.

(3) The prognosis and treatment.

2. A. B., an unmarried woman, aged 25, complains of pain in small of back, extending to sacrum, to the flanks and to the pelvis. These symptoms lead to an examination of the urine, which is discovered to contain both pus and blood in appreciable amount. A further examination takes place with the view of discovering the source of this alteration of the urine.

You are requested to state in detail what would require to be ascertained, in order to avoid error and fix the diagnosis.

3. A woman, on the third day after delivery, had a severe rigor, followed by fever, great tenderness of the whole abdomen, and obstinate vomiting; the pulse was very rapid, the skin dry and hot, and the lochial discharge was suppressed; the abdomen became tympanitic, and the patient lay on her back with her knees drawn upwards. She sunk rapidly; restless delirium preceding death.

Another patient in the like circumstances was also seized with a rigor, followed by fulness in the uterine region, which was painful on firm pressure; her pulse was rapid and feeble, her tongue brown and dry, and there soon came on a typhoid state with low muttering delirium. One of her thighs became swollen, tense, and painful; and her breathing was rapid and oppressed for a day or two before death.

What was the pathology of these cases respectively, and what the morbid appearances which you would have expected to find on dissection?

**DEATH FROM CHLOROFORM.**—The French Medical journals relate the following:—A professor of natural history, aged 30, of strong constitution and excellent health, had suffered for some days from violent toothache. To relieve this he had recourse to chloroform inhalations. One evening, after having been to the play and supped with his friends, he retired to rest at his usual hour, a prey to violent pain. In the morning he was found lying on his side dead in bed, having in his hands a handkerchief held at a little distance from his mouth. There stood on a table by the side of the bed a bottle holding chloroform, the vapours of which filled the apartment. The temperature was very high, and decomposition took place with frightful rapidity. No autopsy was allowed.

## MEDICAL NEWS.

**ROYAL COLLEGE OF SURGEONS.**—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at the meeting of the Court of Examiners on the 12th inst.:—

DEWLIN, H. W., Greenhill, Co. Tyrone.  
EARLE, J. N., Brunswick-street, Borough.  
FAWKNER, J., Manchester.  
GRIFFITH, T., Wellington, Lancashire.  
HOLLINGS, R., Woodlesford, near Leeds.  
JACKSON, J., Leicester.  
ORD, G. R., Brixton-hill.  
SPENCER, H. B., Chippenham, Wilts.  
TOWNSEND, E. R., Cork.  
WAIT, J. S., Bury, Lancashire.  
WALKER, H., Malton, Yorks.

Also, on the 14th inst.:—

CHEESMAN, J., Lewes, Sussex.  
COPESTAKE, W., Kirk, Langley, near Derby.  
CREGEEN, J. N., Castletown, Isle of Man.  
DURHAM, A. E., Guy's Hospital.  
GODRICH, T., Chichester-road, Westbourne-terrace.  
HALLEY, E., St. John's-wood.  
HAMMOND, I., Lower Edmonton.  
KENT, N., Gateshead.  
POPE, J. A., Army.  
ROGERS, G. L., Helston, Cornwall.  
RUTH, A., Aberdeen.  
WOODWARD, M., Pershore, Worcestershire

Also, on the 17th inst.:—

DAWSON, J. E., Sedbergh, Yorks.  
DUNCAN, B. A., Kilkenny.  
HICKSON, J. G., Edinburgh.  
IRVINE, J., Old Aberdeen.  
JEFFCOAT, J. H., Leamington.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, May 13, 1858:—

ATKINSON, HENRY HOPE, Red-hill, Surrey.  
BAUMONT, JOHN, MORTON.  
ELLISON, HENRY, Castle-street, Hastings.  
HARRIS, WILLIAM, Waterford, Ireland.  
HELE, NICHOLAS FENWICK, Pangbourne, Berks.  
OLIVER, JAMES.  
YARDE, WILLIAM, Lambs Conduit-street.

#### DEATHS.

**HOLMES.**—The following extract from an American paper—the *Evansville Journal*—gives a melancholy account of the death of an English Surgeon, homeless and poor, in the hovel of a negro nurse in a foreign land:—"A week ago on Saturday the steamer *Union* brought from Green River an apparently poor and afflicted man, past the age of 30. One eye had been destroyed by a cancer, and the other, by sympathy, was so swollen and otherwise affected as to be sightless. One leg was paralysed, and the poor sufferer seemed utterly helpless, destitute and friendless. No one knew whence he came, nor whether he was bound, except from the desire he expressed to be taken to Memphis. As the *Union* was going no further down the river, he was taken from the steamer and placed on the wharf boat, on the deck of which he lay unattended and uncared for from Saturday evening till Sunday afternoon, when his condition became known to Dr. A. C. Hallock, who visited him and found him in a most afflicted condition—helpless, blind, suffering with pain, and a mind wandering in delirium. The doctor, by intercession with old 'Aunt Hannah,' the black nurse, induced her to give up her only bed and take him in, and attend upon him. He was bathed, clean clothes were procured for him, and his cancer dressed. He refused medicine, appeared to have a perfect professional knowledge of the nature of his disease and condition, said there was no medicine that could help him, and that he only wanted care and quiet. He remained

with his faithful nurse, who was unremitting in her attentions day and night, and he was visited daily by Doctors Hallock and Casselberry, who ministered to his necessities. The progress of his disease was rapid, and he sunk fast under its effects, and on Thursday night he expired, alone in the house of the good negro woman who had given him shelter, with no friend or clergy to soothe his spirit in its last mortal agony. He was respectfully buried by the Sons of Temperance in the Oak Hill Cemetery. On examining his effects after his death, papers were found which proved him to have been Doctor John Pocock Holmes, a member of the College of Surgeons of London. Among them was an original certificate of Sir Astley Cooper, testifying to his qualifications as a Surgeon, with numerous testimonials from other eminent Surgeons of his ability and faithfulness as a member of their Profession. It appeared from other original papers, that he had been, previous to 1827, sixteen years a Surgeon in the employ of the Hudson Bay Company, at their various posts on this continent. In 1827 he was a practising Surgeon in London, holding intercourse with the most eminent men. Among the papers he appears to have preserved with care, is a card of invitation from the Lord Mayor and Mayoress of London to dine at the Mansion-house on the 12th of May, the year omitted. But the papers which he seems to have deemed the most precious, are a package of letters from Capt. Parry, the great Arctic explorer, with whom he seems to have enjoyed a free and cordial intimacy. It appears that the deceased had rendered some useful service as a chemist, and from knowledge he had gained in the Hudson's Bay Company's service, in the manufacture of pemmican for the exploring expedition—for which Capt. Parry gives him much praise, and the Admiralty vote him an acknowledgment of £150. Capt. Parry invites him in free and familiar terms to call at his house in London, and at another time to visit him on board the *Hecla* at the Nore, before sailing. The notes and letters of the celebrated explorer are interesting and valuable as autographs. Among his effects found since his death, were two large and beautiful gold medals awarded to 'Dr. John Pocock Holmes by Medical societies for his valuable inventions of obstetrical and surgical instruments.' There are also a large number of letters from eminent professional men—from the nobility, and Medical and scientific societies, acknowledging the receipt of 'Dr. John P. Holmes' very valuable and able treatise on consumption and asthma."

LEE.—May 6, at South Shields, Cuthbert Marshall Lee, Surgeon R.N. 1810.

OAK.—At his residence, Winchelsea Lodge, Blackheath Park, Kent, on May 19, 1858, Thomas Oak, Esq., aged 73, L.R.C.P. London, M.R.C.S. England, and for twenty-five years one of the Surgeons of the Royal Kent Dispensary. In the earlier and greater part of his life Dr. Oak practised at Greenwich, where, by an honourable career, he acquired fame, confidence and fortune, the latter enabling him many years ago to retire from general practice, to assume the higher and less laborious branches of medicine. He ever loved to exalt and adorn his Profession. Dr. Oak was a man of gentle manners; cultivated and refined mind; fond of literature and the fine arts; and enjoyed the practical study of natural history. Besides a large circle of Professional friends, his removal will be regretted by many out of it. We are given to understand that he has made a bequest to the Royal Medical Benevolent College.

PANTON.—On the 10th inst., at Tunbridge Wells, William Panton, late of the Bengal Presidency.

STRONG.—May 10, in Pall Mall, Francis Pemble Strong, M.D., late of Calcutta, aged 74.

WILSON.—Feb. 17, at the residence of his cousins, Sydney, Australia, Thomas Urwin Wilson, Esq., aged 21, late Student of Medicine at the Leeds School.

#### APPOINTMENT.

Mr. Christopher Heath, Demonstrator of Anatomy at the Westminster Hospital, has been appointed Surgeon to the St. George's and St. James's Dispensary.

We understand that Sir Philip Crampton still continues in an extremely weak condition.

The City of London Lying-in Hospital has been greatly benefited in its funds, says the *Constitutional Press*, by a contribution of 24,000 penny-pieces, collected by a lady of rank within the last twelve months from her friends and visitors.

What Jenner said on reading, in Elysium, that complaints had been made of his having a statue in Trafalgar-square:—

"England, ingratitude still blots

The scutcheon of the brave and free,

I saved you many a million spots,

And now you grudge one spot to me."—*Punch*.

MUNIFICENT DONATIONS.—Alexander Cowan, Esq., father of Charles Cowan, Esq., M.P., has just handed over as donations—£4000 to the Edinburgh Royal Infirmary, £1000 to the Lunatic Asylum, £1000 to the Deaf and Dumb Institution, £1000 to the Blind Asylum, and £1000 to Leith Hospital.

THE CHAIR OF CHEMISTRY IN EDINBURGH COLLEGE.—Dr. George Wilson has withdrawn his name from the list of candidates for the chair of chemistry, and Dr. Lyon Playfair has come into the field.

ELECTION AT THE ACADEMIE DE MÉDECINE.—The election for a member of the Section of Pathological Anatomy has just taken place, in which M. Robin proved the successful candidate, having 40 votes to M. Ménière's 30, and M. Roger's 10.

BIRTH OF A HIPPOPOTAMUS IN PARIS.—The establishment of the Museum of Natural History of Paris possesses a pair of Hippopotami, for which a vast basin of water has been constructed. The female a few days since gave birth to a young one, the first instance of such an occurrence having taken place in Europe. It is true, the calf was accidentally killed by its mother; but the fact is demonstrated that the Hippopotamus will breed in this climate, and in captivity.

THE ELECTION AT THE ACADEMIE DES SCIENCES.—M. Bégin has just lost his election by one vote. The committee had proposed his name first, and M. Jaubert's second. At the election it is necessary that the successful candidate should have more than half the votes of the members present. At the first ballot M. Bégin obtained 27 of 62 votes, and M. Jaubert 21. At the second ballot M. Jaubert obtained 31, and M. Bégin 30 votes. It was objected that this was not decisive, as at least one more vote than the half was necessary; but the president ruled, that as there was one blank ball from a member not voting, this majority was obtained, and M. Bégin lost his election.

THE FRENCH ELECTRICAL PRIZE QUESTION.—An Imperial decree in 1852 instituted a prize of 50,000 francs for the most useful application of the Voltaic pile, fixing five years as the term of the *concours*. In 1857 a commission of eminent scientific persons, with M. Dumas as chairman, and M. Sainte-Claire Deville as secretary, was appointed to examine and report upon the different works. This commission, after the most careful and laborious investigation, has, while acknowledging the value of some of the works produced, come to the conclusion that there is none of sufficient importance to call for the adjudgement of the prize, and recommends adjournment for another period of five years, in the hopes of more complete results being then produced. An Imperial decree sanctions this resolution, and also confers medals upon the most successful competitors, viz. MM. Froment, Duchenne, Ruhmkorff, and Metteldorsdorff. M. Duchenne has also been created Chevalier of the Legion of Honour.

ADDRESS OF CONGRATULATION TO JAMES PAGET, ESQ., F.R.S.—At a meeting of the Yarmouth Town Council, Mr. C. C. Aldred moved that an address of congratulation should be presented to Mr. James Paget, on his appointment as surgeon to her Majesty, and, in the course of a highly-eulogistic speech, said that Mr. Paget, who was a native of that town, and who was well known and highly respected there, had been appointed assistant surgeon to Bartholomew's Hospital in 1847, then Professor of the Royal College of Surgeons, and next as examiner to the East India Company, all of which offices he had gained by his own talents and industry. (Cheers.) Mr. W. Worship seconded the motion, and it was agreed that an engrossed address, sealed with the common seal, should be presented to Mr. Paget by the Mayor.

## VITAL STATISTICS OF LONDON.

Week ending Saturday, May 15, 1858.

## BIRTHS.

Births of Boys, 798; Girls, 752; Total, 1550.

## TO CORRESPONDENTS.

- Mr. Macintosh should consult our last Student's number.  
An Inquirer.—Dr. Cotton's work on "Consumption," and Dr. Semple's on "Cough," will furnish the information required.  
Mr. Crookery, Chapelbown, Jamaica.—The letter and case arrived, but no half-sovereign.  
"A Poor Assistant" can remove the stain produced by nitric, muriatic, or sulphuric acid on black cloth, by sponging it over with hartshorn.—A Dentist.  
Mr. Woake's notice of the operations expected at St. Thomas's last Saturday, arrived after the publication of last week's number. Such notices should be received at the Office before one o'clock on Thursday, at latest.  
Mr. S. K. Lysachy.—We entirely agree with our Correspondent in his abhorrence of quackery, and we wish that his views on the subject were more generally adopted by the weak and credulous persons who are the victims of the empiric tribe.  
Mr. R. Mander.—We would willingly give the information required, but we fear that some of the questions do not admit of a satisfactory reply, as the deficiency alluded to is to be classed among those freaks of nature of which it is difficult to find an adequate explanation.  
F.R.C.S.—We are compelled to decline all communications not authenticated by the name of the writer. If the letter was published with the signature of any respectable Fellow of the College, Mr. Fergusson would, without doubt, reply to it.

**Chemists.**—We have received a copy of the *Cumberland Packet*, containing an account of the legal proceedings taken by a manufacturer of bone manure against the trustees of the town and harbour of Whitehaven, for charging him the same duty on sulphuric acid as on oil of vitriol. After reading the whole of the proceedings, we are convinced that strong sulphuric acid is commercially the same article as oil of vitriol, and that, therefore, the duty was properly charged. In strict scientific language, the term oil of vitriol can only be applied to the thick fluid distilled from sulphate of iron or sulphate of copper; but the sulphuric acid of commerce is never obtained in this manner.

The following is taken from a recent copy of the *Leeds Times*—

"To the desponding of Cure.—Mr. Row, M.R.C.S. and L.A.C., Homerton Dispensary, Ten Minutes from Hackney Station, N.E., London, continues to cure the worst cases of Gout, Rheumatic Gout, Sciatica, Lumbago, Neuralgia, and Tic-Douloureux in a few Hours. He also guarantees the patient against serious suffering from the above diseases in after life by adopting the above treatment. Mr. Row inserts this as a Public Benefit, seeing the advantage taken by the unqualified in this class of diseases through the tardy and uncertain relief by the ordinary treatment. Five shillings is sufficient to cover cost of postage, &c. The poor bringing or sending a letter from the Clergyman of their parish, with 1s. 6d., can be cured."

Do you know anything of this disciple? I cannot see his name in the List. MEDICUS.

## COMMUNICATIONS have been received from—

Dr. MASTER; Mr. C. WILLIAMS; Mr. TIDBOULD; Mr. HARPER; Mr. TRAVIS; Mr. SKINNER; Mr. MACNAMARA; Mr. HADEN; Mr. CROTHERS; Dr. G. SCOTT; Dr. BUDD, Bristol; Dr. THOMSON; Mr. CROMPTON, Birmingham; Dr. RANKING; Dr. LANKESTER; Mr. CROAUFORD; Dr. H. DOBELL; Dr. CAMPS; Dr. W. EVANS; REGISTRAR-GENERAL, Edinburgh; Mr. MACINTOSH; Mr. WOAKE; Mr. HOOBERTON, Dudley; Dr. FURLAND; Mr. BIGGS; Mr. WILKIN, Southampton; Dr. OGLE; Dr. DAVID MADDEN, Falkirk; MEDICUS; THE ROYAL INSTITUTION; THE PRESIDENT AND COUNCIL OF THE PHOTOGRAPHIC SOCIETY; Dr. LAYCOCK, Edinburgh; Mr. A. TALBOT; Mr. S. K. LYSACHY; Dr. HENRY; Mr. R. W. ALDRICH; Mr. WILLIAM CARR; Mr. J. H. WRIGHT; Mr. J. W. IRVINE.

## APPOINTMENTS FOR THE WEEK.

## May 22, Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m.; Charing-Cross, 1 p.m.  
ROYAL INSTITUTION, 3 p.m.: Edwin Lankester, M.D., F.R.S., F.L.S., "On the Vegetable Kingdom in its Relations to the Life of Man."  
MEDICAL SOCIETY OF LONDON, 8 p.m.: Wooden Cooke, Esq., "On the Arrest of Cancer."  
METEOROLOGICAL SOCIETY, 7 p.m.: Anniversary.

## 24. Monday.

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.; Orthopaedic Hospital, 2 p.m.

## 25. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.  
ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m.: Mr. John Tador, "On a Case of Excision of the Elbow," Mr. Coulson, "On Hydatids in the Tibia," Mr. J. Birkett, "On Fibrous Polypus of the Urinary Bladder."  
ROYAL INSTITUTION, 3 p.m.: J. P. Lacaze, Esq., "On the History of Italy during the Middle Ages."

## 26. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Orthopaedic Hospital, 2 p.m.  
GEOLOGICAL SOCIETY, 8 p.m.

## 27. Thursday.

Operations at St. George's, 1 p.m.; Middlesex, 12½ p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.

## 28. Friday.

Operations at the Moorfields Ophthalmic, 10 a.m.; Westminster Ophthalmic, 1½ p.m.; Great Northern, 2 p.m.  
ROYAL INSTITUTION, 8½ p.m.: Dr. E. Frankland, "On the Production of Organic Bodies without the Agency of Vitality."

## EXPECTED OPERATIONS.

King's College Hospital.—The following operations will take place this day (Saturday), at 2 o'clock:—

Removal of breast; division of hamstrings; for the radical cure of hernia; removal of bone from the ilium; by Mr. Fergusson. Excision of the knee-joint. By Mr. Bowman.

St. Mary's Hospital.—The following operation will take place on Wednesday next, at 1 o'clock:—

Vesico-vaginal fistula. By Mr. J. B. Brown.

Westminster Hospital.—The following operations will take place on Tuesday next, at 2 o'clock:—

Strictures (two cases). By Mr. Holt.

## Royal College of Surgeons of England.

The President and Council have the satisfaction of announcing that Dr. BROWN-SEQUARD will deliver a course of SIX LECTURES on the PHYSIOLOGY of the NERVOUS SYSTEM in the Theatre of this College on Tuesdays, Thursdays, and Saturdays, commencing on SATURDAY NEXT, the 22nd inst., at 4 o'clock each day, to which Members of the College will be admitted on entering their names.

By Order,

19th May, 1858.

EDMUND BELFOUR, Secretary.

## To Those who have the Means and the WILL TO DO GOOD.

A Medical Man, of more than average talent and industry, after completing his education at University College Hospital, settled in the West of England, and there married the daughter of a well-known clergyman, the grand-daughter of a still more widely known Doctor of Divinity.

Having struggled through the early difficulties of a Professional career, success had begun to dawn upon him. He had just reached that point at which he might begin to provide for his Family, when he was attacked by indisposition. Unfortunately, disregarding the warning, but obedient to the call of duty, he continued his work almost up to the last moment, and on the 1st of May (within two days from the time when he was compelled to relinquish his labours), he died, at the very prime of his life, leaving his Family utterly unprovided for.

To the loss of a Husband and Father there is thus added the sudden fall from comparative comfort to poverty and distress—the widow and children of him whose hand was ever open to the call of Charity, are now entirely dependent on it for their future support.

On behalf of this Lady and her six little children (the eldest only twelve) thus suddenly plunged into poverty, and most unitted to struggle with its difficulties, an appeal is made to those, who have the means and the will to do good, in the full confidence that it will be responded to by many, who desiring to do charity have not always the opportunity of practising it with the certainty of its being well bestowed.

It is hardly necessary to observe that any aid which could be given towards obtaining admission for either of the two elder boys (aged respectively eleven and twelve years) into any of the numerous public schools would be most thankfully accepted.

The following Gentlemen, viz. :—

WILLIAM CORY, Esq., 15, Chester-terrace, Regent's-park, N.W.

The Rev. HENRY WOOD, Vicar of Stratton, Cornwall.

Dr. BUDD, Physician to the North Devon Infirmary, Barnstaple.

GOLDSWORTHY GURNEY, Esq., Woodleigh, Cornwall; and

JOHN HAYES, Esq., 10, Bedford-place, Russell-square, W.C.;

who are well acquainted with the circumstances of the case, and attest the truthfulness of the statements herein made, have permitted reference to be made to them, and will be glad to furnish further particulars to any one who will take the trouble to inquire.

Subscriptions, however small in amount, will be gratefully received, and may be sent either direct to Mr. Cory and Mr. Hayes, or may be paid to their names, to the credit of the "Dinhnam Fund," at the London and County Bank, 21, Lombard-street, E.C., or any of its branches in London or the County.

In cases where it may be inconvenient to remit subscriptions in the manner described, it is earnestly requested that an intimation of the intention of donors may be sent by post, and arrangements will be made hereafter to collect the amounts without further inconvenience to the parties subscribing.

Unless where otherwise directed, a list of the Subscriptions will be announced in the Daily Papers.

## Cambridgeshire, Isle of Ely, and BOROUGH OF CAMBRIDGE PAUPER LUNATIC ASYLUM.

RESIDENT MEDICAL SUPERINTENDENT.

The Committee of Visitors are desirous of engaging a Gentleman qualified to act both as SURGEON and APOTHECARY (whether possessing a Degree or not), and fully capable to take upon himself the responsible duties of MEDICAL SUPERINTENDENT of the above Asylum, distant about three miles from Cambridge. The person appointed will be expected to devote the whole of his time and energies to the duties of the office, and be precluded from private practice. Preference will be given to a Gentleman who has been accustomed to the care and treatment of Lunatics. The Salary will be £300 per annum, with a furnished house and coals, and an allowance of £140 per annum in lieu of rations. In the event of the Medical Superintendent being married, the Committee would prefer the duties of Matron being performed by his wife, but do not pledge themselves to such course; should, however, this be the case, the Matron would receive a Salary of £100 per annum, and £60 in lieu of rations. The person appointed will have to supply his own plate, linen, china, and other household articles, except furniture, and to provide his own domestic servants.

Testimonials to be forwarded to "The Committee of Visitors," under cover to the care of "The Chairman," Office of the late Mr. King, Solicitor, Cambridge, on or before the 12th day of June next.

Cambridge, 15th May, 1858.

N.B.—It is particularly desired that no application, either personally or by letter, be made to any member of the Committee, or their Clerk; and any such, if made, will not receive attention.

## Gentlewomen, during Illness, may, for

a small weekly payment, receive the comforts of a HOME, combined with the best Medical and Surgical treatment, at the Establishment, No. 1, Upper Harley-street. This Establishment, which was opened in 1850, is patronised by Her Majesty; the Bishop of London is Visitor; and it is managed personally by Mrs. Henry Gibbs, Mrs. Wm. Gibbs, Mrs. Gilbert, Hon. Mrs. Sidney Herbert, Miss Maurice, and other ladies. All information respecting it may be obtained on written or personal application to the Lady Superintendent. Subscriptions received at the Institution, and by the Treasurer, E. MARJORIBANKS, jun., Esq., 59, Strand.

W. C. SPRING RICE, Honorary Secretary.

## Great Northern Hospital, York-road,

KING'S-CROSS.—There is a Vacancy for a JUNIOR-PHYSICIAN. Applications and Testimonials will be received from Candidates by the Secretary at the Hospital of whom particulars may be obtained, on or before May the 28th. Candidates must be Fellows or Licentiates of the Royal College of Physicians of London, not practising Midwifery or Pharmacy.

By Order,

FREDERICK SMITH, Honorary Secretary.

## Parish of Birmingham. — Resident

WORKHOUSE MEDICAL OFFICER.

NOTICE IS HEREBY GIVEN, that the Guardians of the Poor will, at their WEEKLY MEETING, to be held on WEDNESDAY, the 9th day of June next, proceed to appoint a properly-qualified Medical Practitioner to be MEDICAL OFFICER of the Birmingham Workhouse, at a salary of £150 per annum, with furnished apartments, and also coals, gas, and attendance. Drugs and Medical appliances, and the services of a competent dispenser, are likewise supplied by the Guardians.

Gentlemen desirous of becoming Candidates must possess one of the four qualifications named in the Order of the Poor-Law Board, under the title "Qualifications of Officers," and must agree, if appointed, to give one month's notice previous to resigning the office, or to forfeit one month's amount of salary.

The party appointed will be required to devote his time exclusively to the duties of his office.

Candidates are requested to send in their applications in writing, with testimonials, addressed to "The Guardians of the Poor, Birmingham," and superscribed "Application for Appointment of Medical Officer," on or before Thursday, the 3d day of June next. Each application must state the age of the applicant.

No party is to attend before the Board, or any Committee of the Board, unless officially written to for that purpose.

Canvassing the Guardians, either personally, or by agent, or in writing, is strictly prohibited, and will be held an entire disqualification of any Candidate pursuing that course.

By Order of the Board,

19th May, 1858.

JAMES CORDER, Clerk to the Guardians.

## Carriages, New and Second-hand, of

superior style, sterling quality, and finest finish at reasonable rates, for cash, credit, job, or exchange. Circular of prices on application. Credit given when required. Buyers should take carriages on trial, with power to purchase by yearly payments, and thus prove them.

OFFORD'S PATENT MEDICAL MAN'S BROUGHAM MANUFACTORY, 79, WELLS-STREET, OXFORD-STREET.

## The Medicated Cod Liver Oils,

comprising  
OLEUM MORRHUE CUM QUINA.  
OLEUM MORRHUE CUM FERRI IODIDO.  
&c. &c. &c.

Prepared only by SAVORY and MOORE, 143, New Bond-street.

## Liquor Pepsinæ.—A Convenient and

EFFICACIOUS PREPARATION BY

SAVORY and MOORE, 143, New Bond-street.

## For Infants.—The British Feeding

BOTTLE (registered) may be placed in any position without the Food running out. The supply can be regulated by a stop-cock; being electroplated, it may be instantaneously cleaned. Unlike wood, ivory, or bone, it is impervious to moisture, cannot crack or become sour; there is no possibility of the infant drawing air with the food.

By W. T. COOPER, Pharmaceutical Chemist, 26, Oxford-street, London.

Price 7s. 6d., or free to any Railway Station, 8s. 6d.

## Struve's Seltzer, Fachingen, Marien-

BAD, VICHY, and other MINERAL WATERS. Royal German Spa, Brighton. Under Her Majesty's especial patronage. Struve's Pump Room and Promenades, for the perfect dispensing of the most renowned Continental Mineral Waters, is NOW OPEN for the Thirty-fourth Season. The bottled Mineral Waters are sold throughout the year at the Pump Room, and by George Waugh and Co., Pharmaceutical Chemists to the Queen, 177, Regent-street (west side), London; and other respectable Chemists in London and the provincial towns, where a Prospectus, with the highest Medical testimonials, may be obtained, gratis.

CAUTION.—To distinguish these from all other Waters, each bottle is secured by a label and red-ink stamp, bearing Struve and Co.'s name.

## Great Saving in the Purchase of Six

GROSS of NEW MEDICAL GLASS BOTTLES and PHIALS, assorted to suit the convenience of Purchasers, at ISAACS and SON, Medical Glass Bottle Manufacturers.—London Warehouses, 24 and 25, Finsbury-street, Tottenham court-road, London, W.

	s.	d.
6 and 8 oz., any shape, plain, or graduated ..	8	0 per gross.
3 and 4 oz. ditto ..	7	6 do.
1 oz. Moulded Phials ..	4	6 do.
1 oz. ditto ..	5	6 do.
1 oz. ditto ..	6	0 do.
2 oz. ditto ..	7	0 do.

NOTICE.—ISAACS and SON beg to inform the Medical Profession that they have REMOVED to larger premises as above, and hope to be favoured with their commands. A remittance not required till the goods are received. Packages free. Delivered free within seven miles. Post-office Orders payable to "S. Isaacs and Son," at Tottenham-court-road. Bankers: Unity Bank.

## ORIGINAL LECTURES.

CLINICAL LECTURE ON  
DIPHTHERIA AS CAUSED BY THE OIDIUM  
ALBICANS,IN A CASE OF CANCER OF THE SUPRARENAL CAPSULES AND  
MESENTERIC GLANDS WITHOUT BRONZING,  
AND ONTHE CLINICAL INTERPRETATION OF  
PIGMENT DEPOSIT AND PHYSICAL DIAGNOSIS  
OF BLOOD-DISEASES.DELIVERED AT THE  
Royal Infirmary, Edinburgh,

MAY 14, 1858.

By T. LAYCOCK, M.D., F.R.S.E., &amp;c.

Professor of the Practice of Medicine and of Clinical Medicine in  
the University.

*History*—(from report of Mr. Stewart, clinical clerk.)—James Denholm, aged 35, married, admitted into the Royal Infirmary March 19th, states that until two years ago his health was good. About that time he had diarrhoea with frequent desire to go to stool, and much straining at stool, without result. A few weeks afterwards had shiverings and sweatings, and a peculiar feeling of numbness, pricking, and formication, with loss of sensibility in the upper and lower extremities. The arms would become stiff, and he was unable to bend his fingers; if they were bent, they instantly became straight again. This condition was at first almost continuous; but in about three weeks it came on in fits, and at last diminished so much that he resumed his usual employment of labourer. At present the attacks of stiffness only come on when his hands are placed behind his back. Has no headache, but feels giddy occasionally. He continued at work until eight days ago, when the attacks coming on more frequently, and feeling very weak, he was compelled to take to bed. At this time he had sickness and vomiting.

On examination it was found that he slept well, swallowed easily, had no pain after eating, but was flatulent. Bowels regular, motions solid. The abdomen was large and tumid; the parietes thin, so that the contour of the folds of the intestines when distended with flatus, was visible. Increased area of splenic and hepatic dulness was noted. Urine about seventy ounces per diem, of sp. gr. 100.5; no albumen; no sugar. Apex beat of heart not felt, sounds faint and muffled; pulse good. Under the microscope the blood was seen to contain colourless corpuscles in slightly increased quantity. Lungs healthy. No cough or expectoration. His skin under the clothing was pale; the inner surface of the lips pallid, the face unusually brown, but evidently from atmospheric exposure. Particular inquiry was made on this point, and it was ascertained that he was always very much sun-burnt during summer, and did not become fair during the winter. Although considerably thinner than in health, he was not emaciated. His temper was desponding, and he often dwelt upon his nervous sensations. In three weeks after admission the bowels became relaxed, and by April 13, an obstinate diarrhoea had set in, which resisted all the usual remedies. On the 15th he complained of sore-throat, and on examination the fauces were seen to be deeply congested, and covered with white spots. The tongue also had white patches upon it. He still complained of the hyperæsthetic sensations in his arms, and was hopeless as to his recovery. Strength began to diminish rapidly under the exhausting diarrhoea. On April 23 the pulse was 120; deglutition difficult, with a constant burning pain in the throat. On the 24th the pharynx was seen to be covered with a thick yellowish pellicle, and the surface beneath, when it was detached, was raw and bleeding. The pellicle, when a fragment was placed under the microscope, was found to consist of the mycelium and sporules of the *oidium albicans*, with epithelium and pus cells. He was ordered the aqua chlorinata, and a solution of nitrate of silver painted over the fauces with a soft brush. The abdomen was now sunken and flaccid, and there was revealed a flattened tumour immediately beneath the umbi-

licus, in front of the spinal column, having undefined margins. There was no pain in it, nor tenderness on pressure upon it. It pulsated strongly, but with no murmur.

The patient gradually sunk until the morning of the 11th instant, when he died. On the evening before his death he complained of great pain in the epigastric and hypochondriac regions, which was relieved by fomentation, refused to swallow from the pain he suffered when attempting to do so, and passed urine and feces involuntarily. The evacuations were watery, and of a greenish colour. A portion of the pellicle formed upon the tongue, was examined on the 10th, and found to contain the *oidium albicans*.

*Section Cadaveric*—(from report of Dr. Haldane, pathologist to the Infirmary.)—*External appearances*.—Much emaciated. No bronzing of skin, but very slight brownish-yellow discoloration of skin of cheeks, especially under and behind the whiskers. *Head*.—Membranes of the brain natural. Rather more subarachnoid effusion than usual. The substance of the brain was slightly oedematous. The lateral ventricles were enlarged: each contained about 1 oz. of clear serum; otherwise the brain, pons, and cerebellum were quite natural. *Thorax and neck*.—On removing the tongue, trachea, and œsophagus, it was found that a soft yellowish-white pulsatous matter was adherent to the mucous membrane of the tongue, pharynx, and œsophagus. This occurred in some places as a continuous layer, in other places as patches. It could be readily scraped off, when the mucous membrane was found to present a somewhat raw appearance. It was most abundant in the pharynx over the back of the larynx. This matter extended down the œsophagus to within two inches of the stomach. There was a superficial ulceration, of the size of a sixpence, at the lowest part of the pharynx (over the back of the cricoid cartilage) and commencement of the œsophagus, and a similar, but smaller, ulceration on the posterior wall of the œsophagus, nearly opposite the former ulcer, but a little lower down. On examining microscopically the matter found on the mucous membrane, it was seen to consist of the branching filaments and sporules of the *oidium albicans*, mixed with large quantities of somewhat altered epithelial scales. The larynx and trachea were quite natural. The heart and its valves were normal, weight 7 oz. There were no adhesions on either side of the chest. Both lungs were congested inferiorly and posteriorly, and in these situations there was a little blood extravasated under the pleura. Punctiform deposit of black pigment over the surface of lungs. The bronchi contained a good deal of muco-purulent fluid, of a slightly fetid odour; the mucous membrane red and congested; bronchial glands natural. *Abdomen*.—On opening the abdomen a smooth mass of a yellowish colour, partly covered by intestinal coils, was seen lying over the spinal column. This was found to consist of the thickened mesentery. The mesentery was freely moveable, and had not contracted adhesions to any part of the peritoneum. When the mesentery was removed it was found to be converted into a moderately firm mass, about as large as a cheese-plate, and from 1 inch to 1½ inch in thickness. It weighed 26 oz. When cut into the mass was found to be made up of much enlarged glands, having all the appearance of having undergone cancerous degeneration, being of a yellowish grey or pinkish grey colour, moderately soft, exuding on pressure a creamy fluid, which mixed readily with water, and contained on microscopic examination large numbers of nucleated cells, that had all the characters of cancer cells. The disease was confined to the glands, the peritoneal surface of the mesentery being quite healthy. A number of the lumbar glands were enlarged, but to a much less degree, and were infiltrated with cancer. The liver was natural, but close to the neck of the gall bladder was a cancerous gland of the size of a small marble. The kidneys were healthy; but the suprarenal capsules were enlarged. The right capsule was considerably thickened, and when cut into was found converted, in great part, into a mass of cancer, only a few small portions of the normal structure of the gland remained; and these were surrounded and apparently compressed by cancerous matter. The left capsule was not so much enlarged. When cut into, three or four masses of soft cancer of the size of peas were found scattered through it. These masses were softer and more vascular than any of the other deposits, and on microscopic examination the cancer cells were found particularly well marked. The spleen was enlarged, weighing 10 oz. Its substance was rather firmer

than usual, but otherwise presented no morbid appearance. Stomach and intestines natural.

*Comment* (by Professor Laycock).—The case before us has various points of practical interest. The immediate cause of death was the exhausting intractable diarrhoea. Now this supervened coincidentally with an attack of diphtheria or diphtherite. At the onset of the disease, and just before death, we found in the pellicle formed on the tongue and fauces the sporules and mycelium of the oidium albicans, a parasitic fungus found also in muguet,—the epidemic aphtha or diphtheria of infants in France. This is an interesting fact at the present moment, when diphtherite is prevalent, more especially as the pellicle was also found abundantly after death in the œsophagus. I have little doubt that this pellicle was due to the action of the parasite on the enfeebled mucous surfaces of the mouth, fauces, &c. It acts, like all its tribe, as an irritant, inducing increased formation of epithelial scales and effusion of mucus exudation-corpuscles, or plasma: intermingled amongst these are the sporules and the mycelium of the microscopic fungus, as you see in this drawing of muguet (a): the whole con-

stitutes a pellicle or membrane, as it has been termed, varying in thickness and tenacity according to the surface attacked, and according to the condition of the patient. The parasite seems to act upon the capillaries of the subjacent tissue, as when removed blood is not uncommonly effused, and the surface looks raw. Diphtheria is not, however, necessarily limited to one form of disease. We have, in fact, had a case of syphilitic disease of the fauces and pharynx, in which the pellicle containing the oidium was noted, and which seems to have introduced it into the clinical wards. Again, if the fungus multiply in a population at the same time that there is an epidemic of scarlatina or rubeola prevalent therein, that epidemic may be expected to take the diphtheritic form in those cases which are attacked by the oidium. I must add, however, that we have had reasons for thinking that the oidium acting alone will fasten upon the mucous membranes of the mouth and throat, and excite inflammation, and without the formation of a pellicle. Or if it lead to the formation of a pellicle this may be constituted of spores only, with exudation-cor-

puscles, constituting a tougher membrane than that usually found on the tongue and tonsils, and resembling the pellicle of croup. The diagnosis of diphtheritic oidium from ordinary aphtha is founded, first, on the character of the morbid appearance; for in ordinary aphtha the disease is vesicular, and the white specks or patches are ulcers, while in diphtheria they are pellicular, and not ulcerative, while the redness is much deeper than in aphtha. Besides the microscope may reveal the spores and mycelium of the fungus. The development of mycelium is, however, by no means a necessary result of the action of the fungus. This seems to be peculiar to the more advanced stages; at first there is not even a pellicle, only characteristic redness of the affected surface. Dr. Young, our resident Physician, got an attack of sore-throat shortly after one of the patients affected with oidium coughed in his face, while he was applying a remedy to the patient's fauces. Dr. Young had this characteristic deep-red congestion of the fauces, with but a very limited production of pellicle on the pharynx, in which no mycelium was to be discovered. Further, it is probable that, besides the stage of development, the condition of the *habitat* may make a considerable difference as to the morbid products. Thus since warmth greatly promotes the spread of the disease in the form of muguet, the absence of mycelium in diphtheritic croup may be due either to the fact that the weather is cooler when it prevails, or that the mucous membrane of the larynx and trachea, being cooler generally, from the transit of air, is less favourable to the development of the mycelium than that of the mouth, fauces, and œsophagus. Again, the condition of the intestinal mucous membrane seems less favourable to the formation of the mycelium, or of a pellicle upon it. Still inflammation and even ulceration of these surfaces will occur as the result of the irritative action of the parasite, in the same way as ulcerative inflammation supervened in the œsophagus of Denholme. This remark applies also to the bronchial mucous membrane, in which I am inclined to think the oidium may develop an inflammation of the same low type as that seen elsewhere—an asthenic bronchitis with a purulent secretion.

In France a cutaneous form of muguet is observed in children, characterised by a vivid or deep-red erythema and ulceration, more particularly of the inner surface of the thighs, the labia, malleoli, etc. There seems no reason to doubt that the fungus (like others of its kind) may fix upon a suitable portion of the skin. A sucking child with muguet will communicate the disease to the nipple of its nurse. In the case of the syphilitic sore-throat attacked by the oidium, there were also superficial ulcerations of the face of a glary unhealthy character, one at the angle of the right eye, and one at the right angle of the mouth, which were treated locally as diphtheria ulcerations, by a strong solution of borax, and with speedy benefit. How great a share these microscopic parasitic organisms have in the causation of disease, remains yet to be ascertained; but I may mention to you, as a curious fact of the kind, that in a case of asthenic bronchitis, admitted a few weeks ago into the wards, the volvox globator was found in apparent abundance in the fur of the patient's tongue, which was brown, rather dry, and scabrous.

The indications in the treatment of diphtheria are twofold. First, to look to the constitutional condition and treat that; secondly, to aim at the destruction of the parasitic fungus, more especially with a view to prevent its extension along the food and air passages. As to the constitutional condition when a pellicle forms, it is, I believe, invariably asthenic, arising either from a chronic morbid state or from the action of a depressing fever poison on the blood and on the parts affected, as in scarlatina. Like all parasitic fungi, it thrives best where the vitality is low. Where there is not an asthenic state the oidium seems rather to excite a deep red inflammation of the tonsils and fauces generally, and if a pellicle form, little if any mycelium is seen in it. As a general rule, tonics and stimulants, and the so-called "antiseptics," are indicated.

Locally, the remedies which we term parasitocides are the best. There is of these a wide range of choice, but, perhaps, the saturated solution of the biborate of soda is the most efficient and the safest. It is a powerfully destructive agent to the class of fungi; but alkalies generally are parasitocidal. As the oidium is apt to attack the œsophagus, especially in children, and thence extend downwards to the stomach and intestinal canal, the borax may be administered internally also. For similar purposes the chlorate of potass may

(a) From Robin's *Histoire Naturelle des Végétaux Parasites que croissent sur l'homme*, &c. Plate I., fig. 3-7.

be used. We applied the linimentum æruginis (an acetate of copper) in the syphilitic case with good effect. The bichloride of mercury, in the form of a gargle, is also a destructive parasiticide, and is an old remedy for "malignant" sore-throats; but any metallic salt (as the sulphates of zinc, iron, copper) would probably be efficacious. Alkaline gargles and applications, and especially the chlorides (as common salt), have also been found advantageous. Although the nitrate of silver was applied in the case of Denholme, it is not under ordinary circumstances the best application, although the most popular. It is evident that sporules of the fungus may and do pass from one person to another; or, in other words, diphtheria, as due to the *oidium albicans*, is infectious and contagious. It is of importance, therefore, to take the necessary measures for the prevention of its spread. In the case of families of children, the best is undoubtedly isolation of the sick from the healthy.

Next, as to the structural changes found on examination in this case. You will remember how much investigation and research was made during life before we reached anything satisfactory in diagnosis in the case of Denholme. The symptoms referable to the nervous system we found to be in part, at least, suggested; the patient had not, in fact, any true spasmodic affection of the hands, on placing his arms in the position indicated. As the disease advanced, the other symptoms of this class ceased to attract much of either his or our attention, which was mainly directed to the abdomen. After repeated exploration, we could not detect any important change within the large wide belly, and could only infer from the general symptoms that there was structural disease behind the abdominal viscera, probably of the glandular system. Nothing pointed to disease of the suprarenal capsules.

You are aware that Dr. Addison has published a very interesting monograph on the constitutional and local effects of disease of the suprarenal capsules. He observed cases of anæmia of a peculiarly intractable character to be more especially characterised by a dark discoloration of the skin, giving it somewhat the appearance of the skin of a Japanese or Mulatto, as you see in those coloured drawings taken from Dr. Addison's monograph. It has been termed the "bronzed skin." Now, in all these cases Dr. Addison found, on post-mortem examination, disease of the suprarenal capsules. Since the publication of Dr. Addison's monograph, my friend and former pupil, Mr. Hutchinson, has diligently collated a number of recorded cases, in which there was a similar relation between this peculiar darkening of the skin and suprarenal disease, so that it was at last confidently hoped the change in colour might be held to be pathognomonic of the change of structure.

But in the current number of the *Medico-Chirurgical Review*, doubt is thrown upon this conclusion by Dr. Harley of University College, London, who has made careful experimental researches into the effects of total removal of the capsules from small animals. Dr. Harley collates fifteen cases of disease of the suprarenal capsules in which "no bronzing" was observed. On the other hand, he mentions a case in which the discoloration was observed, but without any morbid change in the capsules.

The question is still therefore *sub judice*. But I think that in cases in which you have the group of symptoms described by Dr. Addison and also discoloration of the skin, it is very probable that there is co-existent disease of the suprarenal capsules, although it may be doubted whether such disease be the cause of the discoloration—a combination of causes being required for that. And doubtless the prognosis is unfavourable in such cases, and this knowledge is an important point gained; but perhaps not quite so unfavourable as would appear from the result of Dr. Addison's cases. During the summer clinic of 1856, my class had an opportunity of watching a case presenting the general symptoms described by Dr. Addison, and the indubitable bronzing—the pigment being deposited beneath the mucous membrane of the lips, cheeks, and tongue, as well as so deeply on the face and hands, as to make the man look like a Mulatto; yet the patient recovered under the use of chalybeates, glycerine, wine, and full diet.

Morbid pigment deposit as a symptom of visceral disease is not limited, however, to the suprarenal capsules. Indeed, I think its clinical importance in this respect has been much underrated. Modern observers seem to have almost wholly ignored ancient experience in this respect. If, however, you turn to the old writers from Hippocrates downwards, you will

find that dark discoloration of the skin was formerly associated specially with splenic disease under the term black jaundice. Compare Nicolas Piso, "De Cognoscendis et Curandis Corporis Morbis." Cap. xxviii. De Ictero nigro. He says that cases of jaundice from disease of the spleen are darker than others, and in proportion as that viscus fulfils its function imperfectly, the patient becomes more and more dark, until the body generally is discoloured. He says it is sometimes of a leaden hue, sometimes "fuscous"—i.e. tawny, or of a liver-colour. Modern research, as I will shortly show, has connected pigment-deposit with splenic disease. Casper Bartholin first termed the suprarenal capsules the atrabiliary, from a theory as to their function. It was believed at that time and long previously that the change of colour in black jaundice was due to a black or dark "humour" deposited on the surface—a "succus melancholicus"—derived partly from the liver, but mainly from the spleen. According to Bartholin the overflow of this dark or atrabiliary secretion collects in the capsules, hence the term by which he designated them. Although mixed up with much unfounded speculation by Bartholin, his notion had probably a real foundation in a class of facts like those observed by Dr. Addison.

Let us glance over some of the conditions under which this pigment deposit is met with. 1. There is the ethnic, i.e. the dark skin of dark races of mankind. Now white persons with dark hair and dark eyes, are more apt to manifest morbid pigment-deposit, and in a more intense degree than fair-complexioned people. This is true, *ceteris paribus*, of all forms of discoloration. 2. There are constitutional states, not of absolute health, but not of marked disease, such as that of utero-gestation, or of old age, in which there is a proclivity to morbid pigment-deposit. 3. There are actual cachectic states; true blood diseases, such as splenic diseases and that as described by Dr. Addison, in which there is the same proclivity to pigment-deposit. 4. Pigment-deposit may take place in masses, and occur as the special disease termed melanosis. Now as to the dark-complexioned persons, and as to those with a general state of constitution not perfectly healthy, yet not markedly diseased, it is certain that various irritants to the skin will induce a deposit of pigment. The sun's rays is a familiar example; the heat of the fire striking the legs of aged people will discolour the skin over the shins. Blisters and sinapisms will leave dark stains due to pigment deposit, exactly correspondent in size and shape to the irritant application. Nothing is more common than for eruptive diseases occurring in certain constitutions to mottle the skin with either dark or white spots. If the skin generally be white, then there are dark spots only; if it be generally dark, then the spots may be darker, as you see in this drawing of Dr. Addison's. But the eruptive affection may so alter the pigmentary tissue of the skin that no pigment is deposited where it has occurred. The skin consequently remains white at that point, when all around is dark, and this is *leucopathia*. There are a variety of cutaneous diseases in which this pigmental change occurs. In Ward 11 there is a case of partial nigrities, or melasma of the face in a woman not pregnant, of rheumatic cachectic habit; and on the spots we find sporules and mycelium, like those of the *Microsporon furfur*. It is therefore nosologically a case of pityriasis nigra. In cases of this kind the whole face may become quite as dark as a dark mulatto. Sometimes the black pigment oozes from the skin of the face, mixed with a sebaceous fluid—this is *steatrrhoea nigricans*. In true leprosy there is sometimes a free deposit of pigment, giving the skin a very dark hue. To this group I would refer the dark stains of syphilitic eruptions, and of various cachectic diseases. These are only a few of many illustrations of this law.

It is obvious, therefore, that two conditions at least are necessary to the production of this class of discoloration. 1. A general state more or less morbid. 2. An irritation of the skin, and especially of the pigmental element, from some locally acting cause. Indeed, more than these two are probably necessary,—I refer more especially to some change in the innervation of the skin or affected viscera. Now, in the other forms of more marked discoloration, such as "Addison's disease" and melanosis, the same law probably holds good. There is, however, a more ready deposit of the pigment generally, and in particular the mucous membranes become the seat of it, as well as the exposed or irritated parts of the cutaneous surface. In melanosis, moreover, there is pigment deposit about other morbid deposits, as tubercle, cancer, or plasma.

Now, in all these forms of pigment deposit, from the ethnic to the melanotic, whence comes the pigment? I think the answer must be, that it is deposited from the blood. That there is free pigment matter in the blood has been shown by Heschl and Planer, who found it in the form of small irregular masses in the blood of persons with splenic disease. Professor Samberger, of Wurtzburg, had a case of splenic scorbutus which proved fatal, by hæmorrhage into the brain, in which he found multitudes of cerebral capillaries blocked up by masses of pigment accumulated within them. In fevers, too, in which the spleen is specially involved, there is a pigment deposit. The grey colour of the glands of Peyer and of the mesenteric glands observed in prolonged cases of typhoid fever, is due to pigment deposit. In fatal cases of bilious remittents, the cortical substance of the brain has been found of a pale chocolate or dark grey colour, from the deposit of pigment granules in the capillaries. The liver, spleen, and kidneys are also the seat of a like discoloration. In these cases the pigment is clearly derived from the blood. Indeed, Virchow, Meckel, and Heschl have observed the pigment to appear in the blood in the course of agues. Numerous other illustrations might be given. Free pigment appears, then, in the blood as a morbid state; and the question next arises, how does it get there? Now, the pigment deposit, when morbid, is very constantly associated with anæmia, or with morbid conditions of the blood, such that there is either a deficiency of colouring matter in the blood-corpuscles (leukæmia), or an increase of colourless corpuscles (leucocythæmia), accordingly as you please to theorize. I think it is the blood that is white—leukæmia. In the case under consideration the white corpuscles were unusually abundant; so also in some of Dr. Addison's cases; so in the case of bronzed skin under treatment two years ago in the clinical wards (b). In short, the facts are so multitudinous and decisive as to the connexion between colourless corpuscles and pigment-deposit, that where the deposit is associated with anæmia, you may safely infer a morbid condition of the blood corpuscles or some of them, and consider the case as one in which chalybeates and bitter tonics, as quinine, will be useful. And as to the viscera, in by far the greater proportion of such cases of anæmia or leukæmia, the spleen and lymphatic glands have been found diseased. Thus in Denholme we had disease of the spleen and mesenteric glands, as well as of the suprarenal capsules. Virchow names one form of leukæmia, the *lienal* or splenic. There is now a case of ague in ward 1, with splenic enlargement, in which there is an excess of colourless corpuscles. You have, therefore, three coincident phenomena occurring together so very commonly, as to render the coincidence of considerable clinical importance, namely, disease of the so-called blood-glands; free pigment in the blood, and loss of pigment from the blood-corpuscles. That the one is intimately related to the other is, I think, tolerably certain; and that the spleen is the organ most constantly involved is simply a fact. Now the spleen, like the suprarenal capsules, has had no use found for it by physiologists, because, like them, it can be extirpated in lower animals without any bad results: a lame conclusion from the facts, and contrary to all that we know of the laws of construction of living things. Yet pathological facts unquestionably point to both viscera as involved in morbid states of the blood. What, then, is the conclusion we should draw, in the absence of definite knowledge as to the growth and development of the blood-corpuscles? We must suspend our judgment, and take and use such facts as experience offers, observing in the meanwhile minutely and carefully, so as to extend our knowledge. We shall find, at least, that the defect in colour of the blood-corpuscles, and the presence of free pigment is one thing; the deposit of the pigment in the rete mucosum or elsewhere is another, and perhaps due mainly to causes acting locally. And although free pigment may be shown to exist in the blood, by the fact of its visible deposition, yet it may be present in the blood, and be deposited, yet not *visibly*; that is, it may be deposited in the bronchial glands, beneath the pleura or other internal tissues. This may be the case in certain forms of disease, both of the spleen and suprarenal capsules. And as a general clinical deduction, we may state that the deposit of pigment with symptoms of anæmia indicates, at least, a chronic morbid state of the blood and of the blood-glands.

(b) Since this lecture was delivered, Professor Laycock has found free pigment in the blood of three women with facial nigrities under treatment in the clinical wards: all are cachectic.

We will not lose sight of this principle during the ensuing summer session; for starting from it as a guide to observation and inquiry, and using the microscope as systematically as the stethoscope, we may at last build up a physical diagnosis of diseases of the blood, as well as of the thoracic viscera. The functions of the blood-corpuscles are still to be determined. One of these is, probably, the reception of carbon from the tissues, as well as the transmission of oxygen to the tissues. Now the carbon-eliminating power, as exercised through the lungs and skin, may be interrupted by that same change which modifies the colour of the corpuscles; that is, the absorption of oxygen and the oxidation of the carbon may be impaired thereby. Hence in cases of leukæmia and nigrities the evolution of carbonic acid from the lungs and skin is an important point to be noted clinically.

## ORIGINAL COMMUNICATIONS.

### ON THE RESTORATION OF MOTION

BY THE

### RUPTURE OF THE UNITING MEDIUM OF PARTIALLY ANCHYLOSED SURFACES.

By BERNARD BRODHURST, Esq.

Assistant-Surgeon to the Royal Orthopædic Hospital.

In a paper which was published in the last volume of the "Medico-Chirurgical Transactions," several cases are recounted of partial ankylosis of the hip, knee, and elbow-joints, in which the uniting medium had been ruptured, and where, after a varying amount of time, the power of motion had been successfully re-established. The conclusions at which I had arrived when this communication was presented to the Society were, "That these partial ankyloses might without danger be ruptured, and that motion could be successfully restored." Since that time my opinion has been further strengthened by several other cases of a like kind which have come under my observation.

The affections of joints to which this operation is applicable may be divided into two classes; namely, those in which muscular contraction coexists to so great an extent as to prevent the application of force to the adhesions until tendons and fasciæ have been subcutaneously divided, and those in which the adhesions may be easily ruptured, on moderate force being applied, and without the previous section of tendons, fasciæ, etc.

In all cases of partial ankylosis some muscular rigidity exists. That about the hip-joint may prevent all semblance of motion; the extremity may be in its extended position, and the joint apparently rigidly fixed. At the knee-joint, also, the flexor muscles of the leg may be so rigidly contracted as to prevent the slightest motion of the joint. It is more common, however, to find slight motion (just appreciable motion) at the knee, even with great contraction of the flexor muscles.

Under the influence of chloroform, muscular rigidity may in some instances be so far overcome, that the adhesions may be ruptured without previous subcutaneous divisions of soft structures. Often, however, it is necessary to divide the tense tendons before the adhesions can be reached. Now, it is evident that, if force be applied to overcome great muscular contraction, and at the same time to rupture the fibrous adhesions, the soft structures, namely, the muscles, must yield before the deeper adhesions can be reached. But this is the treatment which was pursued by Louvrier, and was discarded on account of the fatal results induced by excessive violence. He applied so much force, and so suddenly by means of an instrument which had been constructed for this purpose, that muscles were lacerated, arteries were torn through, and bones were fractured. Hence it is that I have divided these cases into two classes; namely, those in which from great muscular contraction, it is necessary to divide tendons and fasciæ, and subsequently to rupture the adhesions; and, secondly, those in which muscular contraction may be sufficiently overcome by the exhibition of chloroform, to enable the adhesions to be ruptured without the use of the knife.

When tendons have to be divided, the punctures are to be allowed to heal before extension is made. Dieffenbach, who was among the first to direct attention to this question, divided the tendons subcutaneously, and immediately afterwards extended the limb forcibly (a). The wounds were consequently made to gape, and they thus became starting points for extensive lacerations of the integument. Some of his operations were, doubtless, so far successful that a crooked limb was made straight, but others were followed by violent inflammation and extensive suppuration, and in some it was necessary to resort to amputation. In none was the motion of the joint restored.

And, again, Langenbeck taught that the employment of anæsthetic agents caused perfect relaxation of the contracted muscles, so that when the patient was under their influence it was not necessary to divide tendons, but that the limb might be extended without fear of rupturing the muscles (b). But this statement involves an error, as was proved by his practice; for serious accidents, such as dislocations, not unfrequently attended these violent operations. Besides, when structural change has taken place in the muscle, when it has been for a long period much contracted, or when adhesions exist, it cannot yield to a suddenly extending force without its fibres being ruptured.

It is, therefore, manifest that it was necessary to reconsider the treatment of partial ankylosis, that neither the danger which had been incurred by Langenbeck should again be encountered, nor the more serious consequences which had resulted from forcible extension with gaping wounds, as had been practised by Dieffenbach, Palasciano, Bonnet, and others.

It has been my first object in the treatment of these cases to remove such impediments to extension as are offered by contracted muscles and by tense fascia; to divide subcutaneously all such structures as would be likely to interfere with the extending process. The wounds were then closed, and reunion was promoted by rest. When this had fully taken place, the full effect of chloroform was obtained and the limb was extended, a suddenly imposed force, or a series of jerks in the direction of flexion being sufficient to cause the adhesions to yield suddenly with a snap, or with a more prolonged tearing sound, or, indeed, without an audible result, and with sudden yielding. But when muscular tension could be entirely overcome by chloroform, and the condition of the limb was such that subcutaneous sections were not necessary, there being neither tense fascia, nor adhesions of the skin, chloroform was administered and its full effect obtained, when, muscular relaxation being complete, the adhesions were ruptured.

If one point is more worthy of attention than another it is the management of the skin while the adhesions are being ruptured. Cicatrices and adhesions should be previously subcutaneously divided, so that unequal pressure may as far as is possible be removed during the act of extension, and especially from those weakest points—the neighbourhood of cicatrices. And should the continuity of the integument be endangered by the extension which may be necessary for the replacement of the articular surfaces, it is preferable to complete this replacement on a second occasion rather than to risk the smallest rent of the skin. As might *à priori* be expected, those cases are attended with the greatest success where the adhesions are ruptured on the application of moderate force, and which yield with a single snap; where the skin is in no measure endangered; where the adhesions are extra-capsular; and where the integrity of the joint is so far preserved that there is no tendency to dislocation. When, however, in consequence of partial dislocation, of extensive adhesions within the joint, or from other cause, considerable force has to be employed, it behoves the Surgeon to be careful as to the direction and extent of the force used, especially when cicatrices exist, that the integument may not, by a violent movement of the limb, be ruptured. With care, this accident will never occur. But, as it is not always possible to destroy all the existing adhesions without endangering the continuity of the integuments, it is more prudent, when great tension has been induced and rupture of the skin appears to be imminent, to remit extension, and to complete the operation on a future occasion. After the subsidence of any inflammation or tenderness which may have been in-

duced, the remaining adhesions will probably yield to gentle pressure, or on the application of slight force.

Again, another point to which I would especially direct attention is, that the adhesions having been ruptured, no further motion or examination of the joint should be permitted. The observance of this rule is, I believe, essential to ultimate success. On one occasion I disregarded it, and, having ruptured the adhesion, I examined the joint to ascertain that its motions were extended and perfectly free. Inflammation followed, which lasted several days. It is unnecessary to examine the state of the joint at this time. The Surgeon may rest assured that the joint is free when he has heard the snap, or when he has felt the limb suddenly yield. His whole aim then should be to prevent inflammation, which is most certainly effected by preventing any further motion of the limb.

Before chloroform is administered, a gutta-percha splint should be moulded to the limb. It may then be allowed to harden while the chloroform is taking effect, and be removed before extension is made. The splint is to be replaced as soon as the adhesions have been ruptured, and is to be worn so long as tenderness continues. And when tenderness has entirely, or nearly disappeared, the limb may be moved gently. It may be necessary to give a small quantity of chloroform before this is done for the first time, or even on two or three subsequent occasions. Each time motion will be borne more easily than the last time, and very soon forcible movements by means of ropes and pulleys may be made. Or in the case of the hip, if the pelvis cannot be otherwise firmly fixed while the thigh is being moved, a chair should be constructed in which the pelvis may be firmly fixed, and the thigh may be flexed and extended to the full extent of motion, or as far as it can be borne, by means of a handle with levers attached to the chair. Also, when the shoulder is the affected joint, some difficulty may be experienced in fixing the scapula firmly. This, however, may be overcome by means of a gutta-percha splint which is moulded accurately to the upper part of the back, the ribs and the lower part of the neck, leaving the joint itself uncovered. When this is firmly bandaged on to the thorax, motion may be given to the upper arm without fear of moving the scapula. But when the tendons have been divided, an extending apparatus is afterwards applied, and extension is carried on as rapidly as possible. When extension is complete, motion is attempted, at first under the influence of chloroform, and passive motion is then continued as has been above explained.

In some instances after rupture of the adhesions, pain is considerable, and passive motion can be borne well; but in others motion cannot be borne, or it cannot be borne with sufficient force to re-establish the use of the joint. It is essential that passive motion should be employed during many weeks, not only that the joint may re-accommodate itself to motion, but also that, where the adhesions are intra-articular, the joint may be, so to say, re-developed, just as a "false" joint is formed by solution of the solid fibrous material connecting the broken ends of a long bone, where perfect union has been prevented by motion of the parts. Also, passive motion is essential that the muscles which have been long motionless may lose their rigidity, and that, from being attenuated and pale, they may regain their fulness and colour. The time which is necessary to this end varies, and is in some measure proportionate to the period during which these organic changes have existed. A short time, however, suffices in a large number of instances to regain some power of motion, and when power of voluntary motion has commenced, it increases rapidly. Even in the "false" joint a capsule may be formed, and synovia be secreted; how much more readily the structures will re-accommodate themselves in the true joint to the purposes of motion will be shown by some cases which I have selected out of many as examples of the restoration of motion in joints after the rupture of adhesions.

But, it may be asked, to what class of cases is this operation applicable? To which I would reply, it is applicable to all forms of partial ankylosis which have resulted from simple forms of inflammation. As, however, various meanings are attached to the terms true, and false, or partial ankylosis, it will be desirable to give an exact definition of the terms, that it may be fully understood what meaning is intended to be conveyed. By some writers true ankylosis is said to consist of intra-capsular adhesions, and false ankylosis of extra-capsular adhesions. While others speak of

(a) Durchschneidung der Sehnen und Muskeln.

(b) Commentatio de Contractura et Aneylosi genu.

true ankylosis, as "loss of motion in a joint," and of false ankylosis as "that condition in which the movements of the joint are more or less interfered with;" while, again, a third definition is, that bony adhesions constitute true ankylosis, while fibrous adhesions or muscular rigidity only form partial or false ankylosis;—therefore it is necessary to define the meanings which the terms "true" and "false" are intended to convey.

There is no doubt that the term "ankylosis" may be applied to rigidity of a joint from whatever cause. In using the term "false ankylosis," however, I wish to be understood as referring to that condition of a joint in which fibrous adhesions have been formed between the articular surfaces entering into the formation of the joint, or which connect the extremities of the bones, whether intra or extra-capsular, in contradistinction to bony or true ankylosis. And without limiting the term "false ankylosis" to fibrous adhesions within or without the joint, I wish for my present purpose to be understood by the term false ankylosis fibrous adhesions within or external to the capsule, producing immobility of the joint.

I am induced to give this definition of the term "false ankylosis" for the following reasons:—That it is not possible to distinguish between adhesions within and external to the capsule until the adhesions have been ruptured, and that the treatment of these two forms of adhesions (intra and extra-capsular) is identical. It is important, therefore, to determine, not that the adhesions are intra or extra-capsular, but that they are fibrous.

**Diagnosis.**—Bonnet wrote, "We have not any certain signs by which we can recognise bony ankylosis." This sentence was written, however, before anæsthetics were in general use in surgery, and at that time it may have been strictly true; for, undoubtedly, occasionally an instance is found where, from the large size of the limb, or from other cause, it may not be possible to assert positively that the adhesion is bony. Generally, however, where true ankylosis exists, the sensation on grasping the limb above and below the joint, and on endeavouring to move one part on the other, is unmistakable. The sensation of solidity which is communicated is never felt when the adhesions are fibrous. Yet, as bony ankylosis is the exception, and fibrous adhesions infinitely more common, the full effect of chloroform should always be obtained before ankylosis is pronounced to be bony. Immobility alone is no sign of true ankylosis. On the contrary, it frequently exists where the adhesions are fibrous. And even where the full effect of chloroform has been obtained, so that all muscular influence has been removed, immobility sometimes remains as great as before. Indeed, I know no certain test which will at once enable true and false ankylosis to be distinguished, except the peculiar and unmistakable sensation which is communicated by solid bony union. But this is certain that, where the slightest motion exists, union is not bony. And again, that when the muscles about a joint are rigid, or the tendons are tense, union is not bony.

**Prognosis.**—When ankylosis is bony, forcible extension will generally be found to be insufficient to restore the straight position of the limb. Excision of a wedge of bone is under these circumstances to be resorted to, to restore the straight position of the limb. Occasionally, however, a bridge of bone may be broken, and the motion of the joint may be restored. Such a case came under my care some time since. Some fibrous adhesions existed, together with a narrow band of bone external to the capsule. The bone yielded with a loud snap, and the limb was immediately free. A very fair amount of motion was restored in this case. Doubtless, a large number of ankylosed limbs are incurable; *i. e.* a crooked limb may be made straight, but motion cannot be restored. Again, in perhaps a larger number, partial motion may be gained after the adhesions have been ruptured; and in a small remainder restoration of motion is complete, or nearly complete. Necessarily the adhesions must be extra-capsular; or when they are intra-capsular they must be slight, that perfect motion may be re-established. I lately saw a young lady whose hip-joint had been ankylosed for nine years. On examination I detected motion, and it appeared to me that the adhesion was very slight. A jerk ruptured them, and the motion of the joint was perfectly free. These adhesions were intra-capsular. No tenderness followed the rupture, and in the course of a fortnight almost the entire range of

motion had been acquired. In this instance voluntary motion to the normal extent was regained; but such a satisfactory result cannot be hoped for, unless the articular surfaces retain their natural form. The more these are altered, the more limited will be the motion of the joint.

Of 32 cases which I have submitted to rupture, the following has been the result:—In 11 instances, complete power of motion, or nearly complete power, has been gained; in 14, partial, but useful, motion has been restored; and in 7 the limb has been rendered straight, and the joint has remained stiff. Of the 11 first-mentioned cases, 8 were of the hip, 1 of the shoulder, 1 of the elbow, and 1 of the ankle. Of the 14 in the second series, 5 were of the knee, 4 of the hip, 2 of the elbow, 1 of the shoulder, and 2 of the ankle; and of the remaining 7, 4 were of the knee, 1 of the hip, 1 of the ankle, and 1 of the elbow.

(To be continued.)

## ON DIPHTHERIA AND ITS TREATMENT.

By THOMAS P. HESLOP, M.D.

Physician to the Queen's Hospital; Professor of Physiology,  
Queen's College, Birmingham.

I have seen in the Medical Journals several notes asking for information relative to the treatment of the angina membranacea or diphtherite, so prevalent in this district during the past twenty months; and, more recently, extensively diffused over a large portion of this country. Similar inquiries of a more private nature are constantly made of myself. About seven or eight months ago the idea struck me, and to a certain extent one or two of my Medical friends here, that probably the tincture of the muriate of iron would be found beneficial in a disorder which had completely baffled every therapeutical method ordinarily acted upon either in this country or in France,—where the experience of the disorder in an idiopathic form has been so much more considerable, during the last hundred years, than in these islands. On reflecting upon the striking alliance of this pestilence with erysipelas, its characteristic tendency to early and profound adynamia, the frequency of severe and often fatal hæmorrhages, and, above all, upon the utterly futile nature of the measures generally employed in its relief, whether derived from traditional medicine or from more modern sources, I felt more and more convinced of the probability of benefit accruing from the administration of that powerful drug. Further reflection upon the nature of the local treatment most in favour in this country, and apparently, almost exclusively in vogue among the French Physicians, led me to the opinion that strong solutions of the mineral acids, and pre-eminently of hydrochloric acid, would be found infinitely more serviceable than the all-popular solution of nitrate of silver. Valuable as this latter agent unquestionably is in the ordinary sore throat, erysipelatous sore throat, angina variolosa, scarlatinal angina, and numerous other modifications of this common malady, it had appeared to me in numerous cases of the membranous angina to be worse than useless. The caustic solution is only useful when it can be brought into immediate contact with the disordered membrane and vessels. And there are obvious chemical objections to its application, to which the hydrochloric acid is not amenable. This latter acts at once as a solvent of the exudation, and as a most penetrative alterative upon the morbid structures. The former can operate no important change in either point of view in this disease; but who does not recognise that the restricted sphere of action of the lunar caustic is one of its peculiarities—one of its merits? The mineral acids in a very dilute form have been employed, time out of mind, in sore throats; and at various intervals, in considerable strength, by some practitioners; but its systematic application in or about the strength of the London Pharmacopœia, to the fauces and buccal membrane in diphtherite, appears to have been nearly altogether neglected, in favour of a measure which, both upon theoretical grounds, and from very extended observation, I feel well convinced has no pretensions to be styled a remedy in that affection.

Opportunities soon occurred to me of putting my views into practice. The results of my trials surpassed my expecta-

tions. I had no longer to tell my pupils of the futility of all efforts to cope with this newly resuscitated pest, when it assumed a really severe aspect. I no longer entered the consultation room with the sentiment that the conference would only end in the display of the weakness of the Medical art. I frequently communicated my success to my brethren, and earnestly besought them to give a trial of the method, conjoined with which I advised the systematic and persevering administration of alcoholic stimuli and other similar agents. In the middle of December I thought it right to bring the whole subject under my clinical class at the Queen's Hospital, and it has gratified me to find that the lecture proved of service to the friends of my pupils elsewhere, to whom the facts were communicated. In January I brought the therapeutics of angina membranacea before the Medico-Chirurgical Society of Queen's College, and adverted to the singular retrogression in our knowledge of this disease, as it has appeared in this country. Though so little known now, it was well understood and admirably described by several British authors a century ago, and by none more ably than by Fothergill. In a number of the *Lancet*, early in December I think, a Surgeon near London reported two cases, treated mainly by the steel tincture, which recovered. I doubt not others have administered, in sheer despair, like myself, the same remedy; but its value is not generally appreciated, and is by most persons denied.

My great fear is, that this method of treatment will be extravagantly lauded, that it will be called by the ignorant specific, and that, on the occurrence of fatal cases under its use, as is inevitable in so virulent a disorder, it will be consigned to the limbo where so many other therapeutical abortions have been thrown. I have been informed of two or three cases in this town where the steel is said to have been administered, but proved inadequate to prevent a fatal termination. I know not what other measures were employed in these cases, or in what doses the tincture was given, but I can very confidently aver that I have had no unsuccessful case since I became aware of the value of this medication. It is of great importance to commence at once the treatment, and persevere to the end, not desisting when the exudation has disappeared, but continuing it until the prostration has given way to the vigour of returning health. Unfortunately Medical traditions are opposed to these measures. With many prudent practitioners a hot and dry skin, with thirst, are and ever will be suggestive, under all circumstances, of the antimonial solution and acetate of ammonia, while the more ambitious school of new physic, basing their practice on a false analogy of the value of chlorate of potash in some forms of stomatitis, will, doubtless, persist in the use of this salt until it shall give place to a more fashionable medicament.

Having stated my great fear relative to this method, I must now allude to the grounds of my trust and belief that a very extensive trial will be quickly made of it. There can be no doubt whatever that the whole treatment of this disorder, as at present practised, is useless, and the greater part of it highly injurious. Many cases have recovered under it, as cases will recover, when of a moderate severity, under every treatment; but experience and theory are equally conclusive against its pretensions as a remedial medication. Antimony, mercury, salines of every order, purgatives, small doses of mineral acids, and tincture of bark, alkalies, and a variety of other agents, combined with local applications, have been administered either on erroneous theoretical principles, or from mere routine; and what does the result show? Our French brethren, who have contributed much additional information upon this subject during the last two years, appear fairly to admit the Medical art to be baffled in its endeavours to arrest a serious invasion of the disorder. My own experience since the month of August, 1856, has been very considerable. I have constantly discussed with my brethren the nature of their experience, and the conclusion I have arrived at I have formalized above. The ordinary treatment is useless, and the greater part of it highly injurious. It is, indeed, impossible to read the observations upon this point in the best books in our language of recent date, without arriving at the suspicion that their able authors have had no experience of this peculiar pestilence. The exudative patches of the later stages of some chronic diseases, of certain epidemics of scarlatina and measles, the grey speckling of fibrin over the tonsils and pharynx, pretty frequently observed in acute sporadic croup, have supplied these authors both with their description of

the disease and with their views of treatment. But this angina membranacea, the malignant or putrid sore throat of earlier authors, is a pestilence in genuine shape, and with well-marked features. After having been unusually diffused with malignant severity over a great part of France during the years 1855, 1856, and played fearful havoc on the coast immediately opposite to England, and especially in Boulogne, it at last crosses the channel, and is heard of here and there in this country in the autumn of 1856. The first and most severe case I have seen, came under my notice in August of that year. I believe it was the first that had been noted in this district. A few cases are soon scattered over the country, but all of the utmost severity, and generally attended with a fatal termination. For a time, as winter advanced, the disorder seemed arrested, but at length, during 1857, notices of its ravages appeared, as observed over many and widely distant parts of the kingdom. It became well established during the latter part of the year, as one of the anxieties of the practitioner in the midland district; and during the last three months, both the medical and general press have teemed with grievous accounts of its inroads. Here, where the disease made perhaps its first, or nearly its first appearance in England during this epidemic, it has for some months worn a milder aspect. In those quarters which it has only recently invaded, it still wears its worst features. It attacks both sexes with equal virulence, and, while specially liable to seize upon children from 5 to 12 years of age, it spares neither extreme of life. It has been seen in the infant at the breast, and my last case was an old man nearly 70 years of age. Like all other epidemic disorders, it is comparatively rare among the rich and those who are surrounded by the conditions of health, and exerts its utmost power in damp and ill-sewered houses among the poor and the wretched. A case occurred in my own house while, owing to heavy rains and the accidental obstruction of my drains by a large quantity of recently upturned earth, there was an overflow of water during the heat of summer in my cellars. The weak child, suffering from diarrhoea, or escaping by an imperfect convalescence from a serious malady, is peculiarly prone to be the victim of diphtherite. My observations lead me strongly in favour of the opinion of the French Physicians, that it is contagious, but not to a high degree. The ataxic phenomena of the malady strike the attention of the most careless. Profound prostration, so disproportionate to the complaint of the throat, which is, in fact, not seldom entirely wanting, comes on early, and remains long after all other symptoms or indications of disease have passed away. The tendency to hæmorrhages, both from the mucous membranes and in the derma, has been a very serious element of it, and one which has brought in its train a fatal termination several times in this town. I have seen two such cases, and in both of them petechiæ were scattered over the body. The tendency to putrescence of the fluids seems well marked, though the frightful fetor of the pulmonary exhalation must be mainly attributed to the decomposition of the faucial exudations, under the favourable influences in which they exist for suffering that change. For it must be remembered that these aplastic matters, which are never known to undergo organization, being apparently completely incapable of taking part in that process, are subjected at once to the operation of heat, air, and moisture. This is undeniably the main cause of the intensely offensive halitus issuing from these patients as is well recognised in France; but, it is equally certain that in the worst cases, marked by highly developed putrescence, a foul ulcerous condition of the fauces complicates the genuine membranous angina. This is termed by our neighbours the ulcero-membranous form.

The mode of death, as in most other pestilences, is by ashenia; and, frequently the fatal event is so sudden and unlooked-for, occurring too after the most trivial exertion and in perfect freedom from all mental disturbance, that we might rightly state actual syncope to be the precise method of death. In spite of many prepossessions to the contrary in the medical mind of this country, apnoea, slow or sudden, is rarely the cause of serious embarrassments, and still more rarely takes part in bringing about the final result. During the twenty months that the disease has been under my scrutiny, in an epidemic idiopathic form, I have seen but one case where manifestations of croup appeared. It was in an intelligent, but unhealthy boy, aged 11. The amount of exudation was enormous. Laminæ after laminæ could be

peeled and rubbed off, but still a dense, almost leathery mass, of a light citron colour, coated the tonsils, velum pendulum, uvula and wall of pharynx. A complete tube-like cast was expectorated, which I showed to the Medico-Chirurgical Society here in October or November, 1886. Croupous bronchitis supervened; and although diarrhoea and general exhaustion aided in overthrowing the vital resistance of the poor boy, yet death was distinctly heralded by the formidable development of asphyxia.

It remains a most interesting question, What place should angina membranacea assume in the nosological cadre? What is its affinity to croup? I am unwilling to enter upon controversial matter in this communication, and, from what I have just said, it will be seen that this epidemic has not given me a special experience of true croup. But I cannot conceal my opinion that the dissimilarity is more considerable than the likeness. Such likeness as exists is that, not of sisters, but of distant relations. Those who see in fibrinous exudation upon the pharyngo-buccal mucous membrane, occasionally extending into the windpipe, a pathological basis for classifying the pestilential disease in which it occurs, with the sporadic croup of Britain, will not be deterred from such a course though I were able to prove the existence of innumerable differences in the vital reactions of these maladies. In the one case we see an acute, sporadic disorder, specially affecting children under four years of age, often attacking the healthiest, and without the slightest apparent prodromata; the most striking characteristic of which is the limitation, in a vast majority of cases, of the morbid products to a small part of the upper end of the air-passages, the only exception to this being the slight exudation pretty generally to be observed, if looked for at the very commencement of the outbreak of the symptoms, on the back fauces and tonsillar region. The patient gets well as rapidly as he became ill, if he only expectorates the exudation as fast as it is formed, and if by nature and efforts of art the pouring out of that exudation is arrested. The labours of art are directed to these ends. We endeavour to diminish the nervo-vascular reaction, we rely upon powerful and often-repeated emetics, and attempt the employment of a blood-changing agent, like mercury, to attack the disease at its source. If the disorder is to entail death, it comes by apnoea. The patient is strangled (a). The Physician, seeing his exertions baffled by a disease whose limits are so narrow, but which has seized the very pathway of life, frequently makes a desperate effort to save his patient, with the aid of the Surgeon. In Paris, where the operation is performed earlier, and not so much as the last refuge of despair, the results of bronchotomy are encouraging. Many are saved from an imminent death. Air rushes into the collapsing lungs, and the sufferer rallies.

How different is the picture of pestilential angina! From what I have already said, its characters are sufficiently apparent, and strongly contrast with those of croup. Epidemic contagions, affecting all ages; attacking those debilitated by previous disease, foul atmosphere, malaria, constant exposure to damp; productive at once of severe and long existing depression; attended by the foulest factor, often by hæmorrhages and petechiæ; the face quickly assuming the aspect engendered by a life-destroying blood infection. A plastic matter is here poured out over a vast extent of the gastro-respiratory mucous membrane; the lips are covered by it, and if a blister takes off the epidermis, a membranous pellicle is apt to be formed on the vesicated surface. The glands of the neck are swelled, and the parts about the soft palate so thickened with exudation, that a faucial gurgling is almost constant; yet there is, in the great majority of cases, the most inconsiderable dyspnoea, a total absence of stridor, and, still more remarkable, complaint of difficult deglutition, is one of the rarest symptoms. When existing, it is trifling when contrasted with the pain attending the common sore throat. If the patient recovers, it is only after a protracted and often interrupted convalescence. Anæmia remains for a lengthened period. If he should be attacked with apnoea, from the extension of the malady to the air-passages, does an operative procedure hold out the same prospect as in croup, highly unfavourable as that is? Even the French Physicians pause in these cases, and allow that the diphtheritic infection gene-

rally contraindicates the artificial opening of those passages, or, at any rate, much diminishes the chance of a good result. We know how sadly unavailing were these measures in the case of the accomplished Valleix and Blache. But the question of the operation rarely arises. The patient is struck down by a blood-poison, and he dies sometimes half-putrid, by way of asthenia.

I am unable to deny that special proceedings must be adopted in those cases in which the extension of the exudation to the windpipe adds a peculiar and fearful element to the troubles of the patient. But those who treat this malady as a modification of croup, will soon see the imperfections of their principles, in the untoward effects of their practice. I fear that, at present, the treatment is conducted by a large number on this basis; and, by the rest, a much larger section of the Profession, on the hypothesis that it is "but a sore throat." I believe both to be fatal errors.

The presence of the disease among us is likely to produce a salutary influence upon the general medical mind of this country. Here is a malady, the local character of which consists in the exudation of fibrinous matter over a wide extent of the body, particularly affecting the system of mucous membranes, and specially the upper portion of the gastro-respiratory tract. Pain is almost wanting. The pulse is neither sharp nor hard. There is moderate pyrexia, incomparably less than in common tonsillitis, and the skin soon becomes cool and moist. The nervo-vascular reaction is then inconsiderable, and quickly yields to manifest and overwhelming depression. Moreover, with all this lymph deposit, the characteristic of the disorder, there is also frequently fatal hæmorrhage! Reflection upon these facts cannot but demonstrate to those who come without prepossession to the study of the phenomena, that however important may be the knowledge derived from modern investigation in relation to the exudation, the product of morbid processes, it is not less necessary now than in older times, to scrutinise the vital changes of the patient, if we are to gain a complete view of his condition, and render ourselves fitting co-operators with nature in her beneficent labours of repair. In this sense, the epidemic of angina membranacea may not be without its value, and afford a bridge between the best medical traditions and modern science.

## COMPRESSION OF TRACHEA BY ENLARGED THYROID.

SYMPTOMS INDEFINITE—LARYNGOTOMY—DEATH AND POST-MORTEM EXAMINATION.

By W. NEWMAN, M.R.C.S.

Helen Spray, aged 15; first seen on the 25th January, 1888.

*History.*—Is a nurse-maid, small and thin for her age; has never menstruated; has been the subject of persistent dyspnoea since she was three years of age; has had for the same time (twelve years) enlargement of the thyroid body; this, she thinks, has increased within the last year.

Says she caught cold on the 21st, and has had increased difficulty of breathing since that time, with cough and hoarseness.

*Symptoms.*—Face rather anæmic; no lividity present; no tenderness on pressure on larynx or trachea; each inspiration is harsh, whistling, and almost metallic in character; cough not frequent, but very harsh and barking. Respirations 30 per minute; tubular breathing in trachea masked by enlargement of thyroid; whistling, harsh respiration in larynx. Physical signs in chest very indefinite; respiratory murmur irregular and indistinct; lungs not properly filled.

No complaint of pain; tonsils and velum slightly red; no dysphagia worth mention. Thyroid body enlarged—both lobes; not very prominent; not tense or hard, and not tender on pressure.

No pyrexia; pulse 100, rather feeble; bowels open; urine in large quantity, and pale; appeared nervous and excitable; had walked one and a half mile just before the visit—this with some difficulty from dyspnoea; complaining much of distress from access of cold. Thermometer 36°.

Emp. sinapis, etc. Anti-spasmodics with sedatives, used in the idea that the attack was principally nervous.

Jan. 26, 11 a.m.—There has been a very bad night; some

(a) I omit the consideration here of those cases in which there is good reason to believe, as Dr. Richardson has so ably shown, that the hyperfibrinous state of the blood conduces to the fatal event in a different manner altogether.

delirium; the description of yesterday is correct as to all material points; on any movement the dyspnoea is much increased; the muscles of the neck start into violent action, and the larynx moves rapidly up and down with each respiration; respirations 30, thoracic; lower part of sternum much depressed at each inspiration; expiration tolerably free, and but little whistling sound with it; no tenderness on pressure over larynx, etc.; no dysphagia; no expectoration. Pulse 120, feeble; no pyrexia; says she is easier than when she arrived home yesterday. Hyd. chlorid. etc.; salines.

5½ p.m.—Much the same up till 4 p.m., then dyspnoea suddenly greater, and some delirium; this has partially subsided; she is restless and uneasy, and on being asked refers her difficulty of breathing to the glottis; percussion dull everywhere over the chest, and auscultation indefinite; speaks with comparative ease, and swallows without difficulty.

9 p.m.—Lying on her side breathing much more comfortably; the same character of breathing still remains, though not so much marked; says she is sleepy; pulse 100, feeble still; respiration 36 per minute, much depression of the lower half of the sternum at each inspiration; considers herself better.

27th, 3 a.m.—I was called up by a message to say she was dying: found her lying on her back, with livid lips and very dusky face; comatose, and not roused without great difficulty; cannot speak; breathing more distressed and much more rapid; loud crowing inspiration; the larynx plunges up and down most furiously, and the sternum is drawn in towards the spine in a most extraordinary way; it appears to give way about its middle, and the most depressed point is between the third and fourth cartilages; respirations 40 in the minute; pulse 120, feeble and thready; noise of mucus in the air-passages, not heard at any prior visit.

It appeared that all this had come on about half an hour before they sent to me. She had been dosing pretty quietly, and the dyspnoea suddenly became more distressing. Examination of the trachea and chest in front with the stethoscope threw no fresh light on the case. The case was certainly not one of mere nervous affection; the symptoms all pointed to the larynx as the seat of disease, though the difficulty was to determine its exact character. The thyroid body, though much enlarged, was not tense, and did not seem so to press on the trachea as to give rise to the excessive dyspnoea. The absence of pyrexia, dysphagia, and of tenderness on pressure, over larynx, etc., to some extent at least, contradicted the idea of laryngitis. Mere spasm of the glottis would not have been so continuous, or have existed for so long a time. Nothing was left but to suppose the glottis the seat of chronic disease (*e. g.* warty growths), and to act on this view. The size of the thyroid body, extending from the cricoid cartilage down to the sternum, would have proved a serious obstacle to tracheotomy; and the excessive lividity of the face promised that the hæmorrhage from divided veins would be great. I therefore opened the larynx at the crico-thyroid membrane, and with apparently good effect. The breathing became less frequent and less harsh, and the pulse sank very quickly to 80, and improved in volume; the face and lips lost part of their excessive lividity, and the restlessness in part abated. The amendment was not permanent; and though the breathing was easier, and the face, etc., less livid, she slowly became more and more comatose, and died at 8 a.m., four and a half hours after the operation.

*Post-mortem examination ten hours after death.*—The larynx was first examined; there was not warty growth or any obstruction whatever to the passage of air through the rima glottidis. The opening of the operation quite patent, and apparently quite sufficiently large.

The thyroid body had no proper isthmus; the two lateral lobes joined in front of the trachea, which they covered from the first ring down to the point where the innominate vein crossed the trachea; the lobes met again behind the trachea, separating it by a flattened portion from the œsophagus; they were large and congested—right lobe weighing 3½j. 3v., left lobe weighing 3ij. 3vj.; total weight of thyroid 3vj. 3iij.; the carotid artery with vein and vagus separated the lobes of the thyroid from the spinal column.

The trachea where it was embraced by the lobes of the thyroid was flattened laterally for two inches; calibre very small; measurement *in situ* gave long diameter (antero-post.) five lines, short diameter (from side to side) two lines. The

lining membrane at the narrowed part slightly reddened, and also slightly œdematous.

The sternum had given way between the junction of third and fourth costal cartilages with it.

No disease in chest. Heart healthy, showing death by apnoea.

The details of this case may prove of additional interest, when taken in connexion with the remarks in the Chest Hospital Reports in the *Medical Times and Gazette* of Feb. 6.

Fulbeck, Grantham.

## NOTES ON AMPHORIC AND TYMPANITIC RESONANCE.

By HORACE DOBELL, M.D.

Licentiate of the Royal College of Physicians, &c.

THE following results of some experiments on the essential acoustic conditions of "TYMPANITIC" and "AMPHORIC" resonance may be interesting to those who have found it difficult to explain the somewhat fickle occurrence of these two varieties of timbre in the percussion sound of the chest during disease:—

Tympanitic resonance requires that the cavity percussed shall be full of air, but shall not communicate freely with external air.

Amphoric resonance requires that the cavity percussed shall communicate freely with external air.

That is, in the former case, the volume of air must be more or less confined; in the latter, it must not be confined at all.

The simplest demonstration of this difference may be made by procuring one of the vulcanized rubber balls, now common as toys. Seal up the small hole in it, and percussion will yield tympanitic resonance; unseal the hole, and the resonance will still be imperfectly tympanitic, the aperture being too small for free communication with the external air; cut the hole large enough that no hissing is produced by the escaping air, when the ball is suddenly compressed, *i. e.* large enough to admit of free communication with the external air, and percussion will elicit amphoric resonance.

## Medical Times & Gazette.

SATURDAY, MAY 29.

### THE STUDY OF FORENSIC MEDICINE.

Now that the Summer Session is fairly under weigh, it may be well to direct attention to the especial importance of the study of Forensic Medicine. At all times a knowledge of the principles of Medical Jurisprudence is to be desired on the part of all who practise Medicine, but it is especially desirable at the present day, when the arts of secret murder have attained a degree of perfection unknown in any previous ages of the world. Yet it is to be lamented that, while the encouragements to other branches of science are neither few nor inadequate, Forensic Medicine is allowed to languish in comparative obscurity; and the results are alike disparaging to the Medical Profession, and injurious to the public. In

proportion to the neglect into which this department of Medicine has been allowed to fall, do the wiles of the assassin and the poisoner acquire vigour and escape detection; and from the absence of the inculcation of sound principles of thought and action on the part of the Medical witness arise many of the lamentable scenes in which our Profession too often figures in Courts of Justice.

We may remark, in the first place, that Medical Jurisprudence, although elevated into a science of late years by the labours of native and foreign writers and lecturers on Medico-legal topics, by no means occupies the position which it ought to hold in our curricula of education. Although lecturers on this subject are appointed at all the Metropolitan and Provincial Schools of Medicine—a circumstance which, so far as England and Wales are concerned, is probably due to the fact that the lectures are required for the qualifications of those who intend to become licentiates of the Apothecaries' Society—yet as to the other examining bodies, the attendance on the courses of Medical Jurisprudence is almost optional. The University of London, indeed, specifies the course as one which the student *may* attend; and an examination on Medico-legal subjects must be passed by the candidate for the London diploma: but the little degree of importance attached by the University to this branch of Medicine may be estimated by the fact, that no special examiner is appointed to test the proficiency of the candidates, who are examined by the three examiners in Midwifery, Chemistry, and Materia Medica. With equal reason might the Examinership in Midwifery be joined on to that of Medicine, or the duties of the Materia Medica Examinership be divided among the Examiners in Chemistry, Botany, and the Practice of Physic. The College of Physicians of London, although specifying Forensic Medicine as one of the courses to be attended by the candidate for its membership, institutes no examination upon the subject; while the College of Surgeons of England, in its requirements for members, makes no mention of Medical Jurisprudence at all, and, of course, has no examination upon it. Hence there must be many members of our Profession who have never received any instruction whatever in the principles of Medico-legal science; and yet they are all liable at any time to be summoned to attend and give evidence in cases of suspicious death, of morbid conditions of mind, of disputed legitimacy, and of a variety of other matters which come within the sphere of legal inquiry, and which affect the lives, the property, and the happiness of multitudes of our fellow-creatures. Even those who do nominally attend the lectures are not uniformly examined upon the topics they have been taught, and hence the lessons of the Professor are often wasted upon inattentive and listless ears, and the precepts he has laid down are either not learned at all or are rapidly forgotten. Those, again, who endeavour to distinguish themselves in this department are neither rewarded for their proficiency nor encouraged to perseverance; and hence their energies are blighted in the bud, and they abandon the pursuit in despair and disappointment.

If we now turn to the practical recognition of the labours of those who devote themselves to Medico-legal pursuits, we shall perceive that our courts of Law are equally indifferent to the interests of Medical Jurisprudence, with the authorities of our own Profession. The Coroner's Court, which takes cognizance of all cases of sudden or suspicious death, might, it would be supposed, offer peculiar encouragements to those who are proficient in matters connected with doubtful cases in Law and Medicine: but the practice of that Court is to avail itself of any Medical or Surgical assistance which may be at hand, without the slightest reference to the competency of the parties who are called as Medical witnesses. As we have shown that many members of our Profession receive no instruction in Medical Jurisprudence, it is obvious that, although they are not to be blamed for ignorance on subjects

which they have not been taught, still they are incompetent to assist in conducting complicated judicial inquiries, and yet the theory and practice of the Coroner's Court are that all Medical Practitioners are upon the same level in regard to competence, and that any person holding any Medical qualification whatever is fitted to pronounce opinions on matters which might puzzle an Orfila or a Christison! This fusion, as it were, of all the members of the Profession into one crucible on the part of the Coroner, arises from the desire on his part to distribute the fees which he has the power to bestow among as many Medical witnesses in the vicinity as possible, and thus to avoid the imputation of favouritism and partiality. But while this system may be defended upon the principle of equal distribution, it is wholly unsupported by any sound reasoning whatever. If a man wishes to secure the services of an artist, or an architect, or a solicitor, or a barrister, he does not apply to a person in any of those Professions merely because he may happen to live next door to him, or in his immediate vicinity, but because he is acquainted with his talents and reputation. Not so, however, with the Medical witness who is called upon to give evidence involving innocence or guilt, natural or unnatural deaths, the existence or non-existence of poison in the viscera or tissues of the dead, and other similar difficult and often complicated problems. Without the slightest disparagement to any member of our Profession, we may assert that all are not equally competent to deal with such questions: some are more conversant than others with the details of chemical analysis; some are better acquainted than others with the distinctions which characterise healthy as opposed to morbid tissues; some have had greater experience than others in the practice of courts of Law; some have devoted more attention than others to the literature as well as the practice of Medical Jurisprudence; and yet all are amalgamated together by the Coroner as equally reliable authorities. Such a course of proceeding is quite destructive of any tendency on the part of the members of our Profession to attain special proficiency; and he who has devoted many laborious years to the pursuits of Forensic Medicine, will find himself placed in exactly the same category, as far as regards the emoluments derivable from the Coroner, with the youth who is fresh from his studies, and who perhaps has never been taught Medical Jurisprudence at all.

In the higher courts of Law the same system, or rather want of system prevails. All Medical practitioners are considered alike competent to offer opinions upon the most complicated and difficult questions; and when they are sometimes caught tripping, as they occasionally are, by an ingenious or unscrupulous counsel, great is the merriment caused at the expense of the unfortunate doctors, and great the contempt poured upon Medicine and its Professors in general. Now this would not be the case if the principles of Medical Jurisprudence were better and more systematically taught; if examinations on the subject were held by all the Medical examining bodies; if special rewards were held out to those who had attained proficiency; and if those only who possessed some special knowledge were employed as witnesses in the Coroner's court, and in the other Law Courts. We would not by any means exclude any Medical witness whatever from expressing his opinions upon the facts of any case which may have fallen under his observation; but we maintain that the search for poisons, the examination of morbid structures, the distinctions between natural and violent deaths, the determination of the soundness or unsoundness of the human mind, and other similar matters, should be reserved, in the highest resort, to those who have paid some special attention to such subjects.

Before quitting this subject for the present, we would again urge a point to which we have adverted on previous occasions, namely, the propriety and the expediency of appointing, at all important trials involving Medical ques-

tions, Medical witnesses of high character and scientific reputation, who might assist the deliberations of the Judge and the jury in detecting crime, in punishing the guilty, or in absolving the innocent. Such Medical witnesses, or assessors, should not be drawn up in hostile array against one another, paid for maintaining contrary views like lawyers, and alternately abused by the counsel for the prosecution and the defence; but they should be treated as honourable and independent men, sworn to give the best evidence in their power for the promotion of justice; and they should be protected by the Judge in the unprejudiced expression of their opinions. The principles of law are not perfect, nor are Judges infallible, yet those functionaries receive, and very justly, the respect of the community; and there is no reason why the opinions of Medical Judges, of known character and integrity, should not be treated with equal respect and deference, to that accorded to the dicta uttered from the judicial bench.

### THE WEEK.

A CASE of considerable interest in a medico-legal and psychological point of view is now occupying the attention of the new Court for Divorce and Matrimonial Causes. A lady seeks for a judicial separation from her husband on the ground of cruelty, and she alleges that he has beaten her on numerous occasions, has refused to allow Medical attendance to her sick child, has forbidden one of her children to be baptized, and has committed other harsh and unkind acts. These allegations are partially admitted on the side of the husband; but it is shown that he has laboured under insanity, for which it was at one time necessary to place him in confinement in a lunatic asylum, and it is asserted that the acts of violence and cruelty occurred while under the influence of maniacal delusions, but that when restored to reason he is a kind and attentive husband, and an industrious man of business. In the proceedings at the Court last week, he conducted his case himself, and appears to have manifested great ability—reversing, in this particular instance, the common saying that “a man who is his own lawyer has a fool for his client.” It will be for the Court to determine whether he has ill-treated his wife while in a sound state of mind, or whether the alleged ill-treatment is merely the result of insanity, and, therefore, to be regarded as an effect of disease.

It gives us great pleasure to announce two important improvements upon the mode of examination hitherto conducted in the University of St. Andrew's. The first is to adjudge honours to those Graduates who have shown most proficiency in their written and oral examination; and the second is to test the practical knowledge of the candidates by taking them to the bedside of patients, and there requiring them to form their diagnosis of disease. The mode in which this examination has just been conducted, is described in another part of our Journal; and we consider that the new system is highly creditable to Dr. Day and the other Professors of this, the most ancient of the Scottish Universities.

The writer of a letter in the *Times* last week draws attention to the occurrence of three deaths in one family in the Hyde-park Barracks; and in connexion with this circumstance, he describes the sanitary condition of the locality. “On the right hand side of the public street of Knights-bridge,” he writes, “is a high dead wall. Some twenty or thirty feet behind that wall are the buildings in which the officers, men, women, children, and horses of the Life Guards and Blues live. The narrow, close space between this wall and these buildings is used as a receptacle for the manure of

the stables. The latrines of the men and officers, the urinals, and the airing-ground for the notorious wooden conveniences which still infect the barrack-rooms by night and this small yard by day, are also located therein. . . . The steam and smoke of these abominations may be seen any morning curling heavily over the dead wall, and infecting the air of the neighbourhood. The wonder is not that three poor children have died within the last fortnight of scarlatina behind that wall, but that the vicinity of the place is not chronically infected with typhus.” The writer, in the same letter, intreats the Inspector-General of Cavalry, whom he often sees riding in Rotten-row, to cross over and inspect the barracks. It is, indeed, a disgrace to the authorities that such a state of things is allowed to exist, and that not even a fatal epidemic can awaken the slumbering energies of the Horse Guards. Since the first letter to the *Times* was written, it is recorded that a fourth child has died of scarlatina in the same locality, being the whole of the children cut off in one family!

In the very able Clinical Lecture by Dr. Laycock, which is published in our present number, that Physician draws an analogy between Diphtheria and Muguet, and he shows that both these diseases are due to the presence of a parasitic fungus on the surfaces of the mouth, fauces, and other mucous structures. These views are particularly interesting at the present moment, when the subject of Diphtheria occupies so much of the attention of the Profession. In the same lecture it will be seen that Dr. Laycock does not entirely admit the theory that bronzed skin is due to disease of the suprarenal capsules, but that he refers this, and other forms of discoloration of the skin, to some hitherto unexplained changes in the constitution of the blood.

### MILITIA SURGEONS.

On the 13th inst. a deputation from the Militia Surgeon's Society of Great Britain and Ireland waited on Lord Derby by appointment, at his official residence, Downing-street. The deputation comprised the following Militia Surgeons, viz. Mr. Hansard, Oxford; Mr. Borlase Childs, Royal London; J. McCann, M.D., 3rd Middlesex; Dr. Barr, Northampton; J. Guy, M.D., 3rd West York; Mr. Mitchinson, North Lincoln; Mr. McCormack, M.D., Bedford; Mr. Isaacson, Huntingdon; R. H. Courtenay, M.D., Donegal; Mr. Fernelley, South Lincoln; T. G. Harrison, M.D., 6th Lancashire; Mr. Curtis, East Kent; and Thomas McCall, M.D., Edinburgh. They were accompanied by Lord Claude Hamilton, the Hon. Mr. Tollemache, M.P., Lord James Stuart, M.P., Colonel Stewart, Mr. Watson Taylor, M.P., the Duke of Cleveland, Mr. Ker Seymer, M.P., Mr. Price, M.P., the Marquis of Salisbury, the Earl of Bandon, Colonel French, M.P., Mr. Fagan, M.P., Mr. Adams, M.P., Major Sibthorpe, M.P., Mr. Beecroft, M.P., Serjeant Deasy, M.P., Sir Montague J. Cholmeley, M.P., Captain Grey, M.P., Mr. Kelly, M.P., Colonel La Zouche, the Duke of Buccleugh, Mr. Hassard, M.P., The O'Donoghue, M.P., Mr. McCarthy, M.P., Mr. Hatchell, M.P., Mr. Darby Griffiths, M.P., Sir M. Stewart, Mr. Brady, M.P., the Marquis of Donegal, Colonel Barnard, M.P., Mr. Heard, M.P., Colonel Duncombe, M.P., Colonel Smith, M.P., Colonel North, M.P., Sir H. Rawlinson, M.P., and Mr. Roebuck, M.P., General Peel, and Col. the Hon. P. W. Talbot (private secretary to Lord Derby) were present.

Lord CLAUDE HAMILTON, M.P., having introduced the deputation, stated the object they had in view in coming before his Lordship, namely, to improve the position of Militia Surgeons of disembodied regiments; which, under the present system is not only anomalous, but unsatisfactory and uncertain. Lord Claude Hamilton proceeded in very able and forcible language to describe the hardness of compelling, as at present, Surgeons to reside at their Head-quarters when

disembodied, without any fixed remuneration; what they did receive being inadequate; and in many instances they expended all they received in medicines, surgical appliances, etc. He proceeded to show that by placing them on the permanent staff the Government would be put to no additional expense, and they would secure the services of Medical officers perfectly conversant with details, and responsible for the proper discharge of the same. He then called on some Militia Surgeons to corroborate by statistics the statement he had made.

Drs. McCormack, Guy, Courtenay, and Hansard severally addressed his Lordship, and fully established the hardship of their position, receiving but a very scanty allowance for their duties, unable to procure either public appointments or private practice to any extent, as the public are averse to employ Medical men exposed to the chances of being called on at a moment's notice to serve in camp, garrison, and in many instances to go abroad. They also read statistics showing how they could obtain a fixed pay on the staff, and be employed to discharge every military duty with no extra expense to the country.

After an hour's interview, Lord Derby and General Peel promised the deputation that if they could support their case by returns, for which every facility would be provided, the Government would willingly accede to the prayer of the memorial.

The deputation then retired, thanking his Lordship for his courtesy and patience in listening to the deputation.

## UNIVERSITY OF ST. ANDREW'S.

THE following gentlemen having previously obtained the degree of Doctor of Medicine, have been placed in the List of Honours:—

### Class I.

BOWEN, ESEEX, late Royal Artillery.  
COOK, HENRY, H.E.I.C.S.  
POTTER, HENRY, Limerick.  
RULE, SAMUEL, London Hospital.

### Class II.

In the examination for honours, the following points are taken into consideration:—

1. The manner in which the candidates answer the questions contained in the five examination papers for ordinary degrees.
2. The manner in which they answer the questions contained in an additional general paper, embracing Comparative Anatomy and Physiology, the higher departments of Human Physiology and Pathology, and Medical Jurisprudence.
3. Their readiness in diagnosis by the bedside.

As this is the first examination for Medical Honours in the University of St. Andrew's, we subjoin a copy of the general Examination Paper, and a sketch of the mode in which the Clinical Examination was conducted.

### EXAMINATION PAPER FOR HONOURS.

1. Explain the mechanism by which the eye is enabled to adapt itself to different distances.
2. Give a general sketch of the organs and process of respiration in birds, reptiles, amphibians, and fishes.
3. Describe the organs and process of reproduction in insects, and state what peculiarities in reference to reproduction are exhibited by bees and aphides.
4. What relationship has been established between the cystic and cestoid entozoa? Describe the experiments which led to the discovery of this relationship, and show the practical value of the facts which have been ascertained.
5. A stomach with its contents is sent to you for examination in a case of suspected poisoning. State what process you would adopt in searching for prussic acid, opium, oxalic acid, sugar of lead, or strychnine.
6. What symptoms and physical signs would lead you to suspect fatty degeneration of the heart? Describe minutely the appearances you would expect to find after death, and explain the origin of the fatty matter.

### SKETCH OF THE CLINICAL EXAMINATION CONDUCTED AT THE ROYAL INFIRMARY, DUNDEE.

I. A Medical case assigned to each candidate by the Examiners, observations made during a limited time, and afterwards reported on *visd voce* from notes taken by the candidates at the bedside.

II. Three special types of disease observed and reported on by each candidate in succession as follows:—

- a. Encephaloid tumour of liver to be examined by physical diagnosis only. Time allowed, one minute and a half.
- b. Moderate cyanosis, feeble circulation, heart's sounds normal. Probable emphysema of lung. Time allowed, one minute and a half.
- c. Subacute phthisis pulmonalis, well-marked hectic. Time allowed, one minute and a half.

III. Eleven specimens of urine, including normal and abnormal types, to be observed and reported on *visd voce* in the presence of the examiners.

It has been resolved that if a candidate does not acquit himself creditably in the Clinical examination, no amount of excellence in the other departments will entitle him to a place on the list of honours.

## PROGRESS OF MEDICAL SCIENCE.

### Selections from Foreign Journals.

#### STATISTICS OF OPERATIVE MIDWIFERY IN PRIVATE PRACTICE.

By Dr. MEISSNER.

This is a report by the great Leipsic veteran, on the results of his thirty-five years' midwifery practice, as far as operative midwifery is concerned. He observes, that a review of private midwifery practice must be taken from quite a different point of view to that of a public institution; for while, in the latter, the bulk of the cases are examples of natural labour, the private practitioner is only consulted, as a general rule, when the case has become pathological. [These observations are, of course, only applicable to the mischievous continental practice of leaving cases in private practice to the almost exclusive care of midwives, the Physician only being called in when the case has assumed a serious aspect, and, of course, frequently too late.] Moreover, in the Lying-in Hospital, the Physician treats his cases in a suitable locality, with all he wants at hand; while, in private, the practitioner is called miles away to neglected cases, having insufficient appliances, and is forced to treat his cases under the most disadvantageous circumstances.

Dr. Meissner's observations relate to 3811 women, who, he says, gave birth to 3980 children, as 136 were twin, and 2 triplet births. But there is here obviously some error in the numbers, as these do not correspond with each other. Of the 136 twin-births, in 54 there were 2 boys, in 35 2 girls, and in 47 children of both sexes. Of the triplets, in one case there were 2 boys and 1 girl, and in the other 3 girls. These 3811 labours called for operative interference in 3025 instances, dynamic aid being required in 924 of these to effect change of position. There were 1863 forceps operations (!), this instrument being required in 5 other instances for the removal of separated fungoid or polypous tumours. Turning was performed 351 times, extraction 247 times, perforation 32 times, the induction of premature labour 20 times, the Caesarean operation 6 times, *accouchement forcé* 55 times, polypos operations 6 times, placenta separation or deliveries 447 times. 2086 boys and 1684 girls were born at full time, while there were 265 premature births or abortions, and 24 moles and polypi. 399 children were born dead, and of those living 36 died within fourteen days. Twenty-five mothers died either before or during labour, or within sixteen days after it.

Turning.—Although this, when performed at the proper time, is usually an easy operation, executed within a few minutes, yet of the author's 351 cases in only 222 did it prove completely successful for both mother and child. In 104 cases the child was born dead, in 2 cases the mother

died from the delivery, and in 2 after this had taken place. This issue is chiefly to be attributed to the ignorance of midwives in the detection of cross presentations, and the delay that elapsed before aid was obtained. Dr. Meissner prefers turning by one foot, unless there is some indication for hastening the delivery. This rule is of especial importance when multiple births are expected, so as to avoid getting hold of two feet of separate children. In one of the author's cases of triplets all the children presented cross-wise, and six lower extremities were felt. All the children were safely delivered by operating upon one foot at a time. The one-foot delivery also gives the child the best chance of being born alive. *Cephalic* version is preferred by some practitioners, as giving the child the best chance; but it can only be tried when hastening the delivery is not an object. The author resorted to it successfully in 6 cases. In 4 of the 351 cases turning was performed by *external manipulation*, and in 3 by *spontaneous* version, the buttocks being forced by the presenting shoulder into the pelvis, and all the children being born dead.

**Forcipes Operations.**—Of 1863 cases, in 1750 the head was the presenting part; and in 113 the forceps were used for its delivery in other presentations. Of the 1754 children delivered, 99 were born dead, i.e. nearly 12:19. This, in an operation which, carefully performed, can hardly be considered dangerous to life, is a high proportion; but the child had, in fact, not unfrequently died during pregnancy, and was in advanced putrefaction on delivery. In 10 instances the child was hydrocephalic or dropsical; in 3 the mother was already dead; there were 5 cases of *spina bifida*; 7 deaths took place from prolapsed funis, and 3 from the arm and head being tightly wedged in together. In 4 instances the mother had suffered from repeated convulsive paroxysms. In other cases the application of the forceps had been repeatedly attempted by preceding practitioners, or the passage was narrowed by the presence of tumours. Dr. Meissner remarks, by the way, that the separation of the epidermis is not always a certain sign of the death and putrefaction of the child, as it may be produced by an acrid condition of the *liquor amnii*.

**Extraction.**—This was performed in 247 cases, and became necessary when, in breech, knee, or foot presentation, the child's life was threatened by cessation of pain, faulty position, or prolapsus of funis. Only 145 of the children were born living; but then, 13 had died through pressure on the funis, before the author's arrival; 18 were in a state of putrefaction, 10 were already born except the head, 8 were immature, and in 5 others there was hydrocephalus, or other form of dropsy. In 42 instances extraction had to be performed on account of cessation of pain after turning.

**Perforation.**—In his thirty-six years' practice, this operation has only been performed by the author thirty-two times, and he had attended 3299 labours before he had his first case. He has always followed the maxim laid down by the chief German practitioners, of never proceeding to the operation until assured of the child's death; and it has several times happened to him to see living children born in cases which have been left for days together to the powers of nature, and which in previous labours had been delivered by perforation.

**Premature Labour.**—So much has the performance of the operation for premature labour limited that of perforation, that while to the year '42 he had had to resort to perforation in twenty-eight instances, he has during the subsequent fourteen years only performed it four times. He has never induced premature labour prior to the thirty-sixth week, and has never found this too late, the bones continuing thus long sufficiently soft and yielding to accommodate themselves to the narrowed pelvis. When the reckoning is uncertain, he performs the operation thirty-six weeks after the last menstrual period.

**Forced Delivery (Accouchement Forcé).**—By this term the author understands the whole series of operations (as artificial dilatation of the os uteri, bursting the membranes, turning, extraction, or removal of placenta), which may be required for delivery when the further continuance of pregnancy is dangerous to mother and child. It is especially called for in certain cases of eclampsia, placenta prævia, and obstinate vomiting. He enumerates under this head two instances of opening the adherent os uteri by means of the knife, and eight cases of its forcible dilatation. This last procedure was resorted to because, after the labour had continued three or four days, in place of dilatation of the os uteri, general debility

and delirium set in. The author has resorted to it fifty-five times during thirty-six years. In thirty-three of these cases both mother and children did well, although, as the dilatation was usually undertaken for placenta prævia, most of the latter were born some weeks too soon. As the majority of cases (31) were examples of placenta prævia, in which hæmorrhage had continued long before the patients were seen by the author, it is not surprising that ten of the mothers died; but another statement of the author, that even when he arrived at his patients he plugged the vagina, and awaited pains before proceeding to deliver, is somewhat extraordinary.

**Cæsarean Operation.**—Of the six examples of this that have fallen to the author's lot, five were performed on mothers being already dead, the children being saved in none. In the case of operation upon the living subject, both mother and child lived.

**Placenta Removals.**—The number of these—447—must seem very large; but it is to be remarked that perhaps not one-tenth of these cases were examples of abnormal adhesion requiring separation, the placenta being frequently detained from other causes, preventing the success of the ordinary manipulations, as "stricture of the uterus," spasmodic contraction of the uterus from too early interference, etc.

**General Results.**—Of the mothers, 41 were lost, 25 during, and 16 after delivery. Of the former 25, 11 were already lifeless when seen; and of the 14 others, 1 died from rupture of the omentum with internal hæmorrhage, 10 from placenta prævia necessitating forced delivery, 2 from nervous shock after favourable labour, and 1 from hæmorrhage. Of the 16 mothers who died after delivery, 1 died from cancer of the stomach, 1 from pneumonia, 3 after repeated attacks of eclampsia, 1 from putrescence of the uterus, 1 from typhus following the birth of a putrid, premature child, 4 from puerperal fever following operative procedures, 1 from "paralysis of the lungs," 3 from the consequences of loss of blood, and 1 after several hours' operative attempts by a country practitioner.

Of the children, 399 were born dead, as already stated, under the various operations. Besides these, 36 died within the first fourteen days after birth; viz., 4 from debility from too early birth, 6 from atelectasis pulmonum, 2 from trismus, 1 from fissure of the cranium after a forceps operation, 1 from chronic hydrocephalus, and 2 from want of breast-milk.

After remarking upon the remarkable sequences met with in practice of unusual pathological occurrences, and of the operations required for their relief, the author observes, that, as a general rule, forceps operations are found to be most frequent in cold, changeable weather, which induces rheumatic affections of the uterus, not only rendering the dilatation of the os very painful, but delaying its accomplishment for days. This condition may be often prevented by clothing warmly the lower part of the person; and when it is present it should be treated by Dover's powder. The standing too much over the fire, also, may, by over-heating the abdomen, lead to a plethoric condition of the anterior wall of the uterus, which may not be without its influence in inducing morbid adhesion of the placenta. Such an occurrence is best prevented by abstaining from this practice, and bathing the abdomen with cold water. When adhesion has taken place repeatedly at the same place, in consequence of an indurated condition of a portion of the uterine wall, we should, after the termination of the puerperal condition, endeavour to induce absorption by mild mercurial or iodine frictions, tepid baths, together with hemlock and mallow injections. If these do not succeed, the baths at *Krankenheil*, near *Tolz*, in *Bavaria*, which have been found so useful in fibroid and hypertrophy of the uterus, should be tried.—*Monatschrift für Geburts-Künde*, Band ix. pp. 19—72.

## OPERATION FOR ENTROPION.

By Professor THIRY.

A scrofulous woman, aged 26, applied to M. Thiry's clinique, in consequence of a double entropion of both eyes, which she had suffered from during four years. She had been frequently operated upon, with the effect of aggravating rather than relieving her condition. The spasmodic contraction of the orbicularis almost closed the orbital aperture, and the eyelids, so turned in as to be no longer visible, had induced severe conjunctivitis and keratitis. Extreme photophobia and epiphora were present. She had from time to

time obtained temporary relief by the avulsion of the eyelids, when M. Thiry determined to attempt a radical cure. Observing that the eye was very deeply placed in the orbit, and that the inter-palpebral aperture was very narrow, he abstained from imitating the practice of the surgeons who had before seen the case, and who had diminished the length of the palpebræ by resection of flaps of skin. These anatomical dispositions were, in fact, the direct and immediate cause of the entropion, the production of which had been favoured by the presence of scrofulous inflammation. The spasm accompanying this would induce the inversion of the too narrow border of the eyelids, to which the globe of the eye, situated too far behind, could not give sufficient support; the operations already performed having only aggravated the state of things.

Under these circumstances, the following was the procedure adopted by M. Thiry for the left eye, this being the worst of the two. The patient being seated opposite the light, and an assistant supporting her head, and raising the upper eyelid as much as possible, M. Thiry, depressing the lower lid with his left hand, armed with a narrow curved bistoury, prolonged the palpebral aperture at its external angle by about three or four lines; then passing the knife again into the wound, he divided the palpebral fibres which served as a point of attachment for the orbicularis muscle. The palpebræ became immediately greatly relaxed, their free edges together with the eyelids assuming their normal position as if by enchantment. A little charpie was forced deeply into the wound, in order to prevent too rapid cicatrization; while the eyelids were kept gently separated by means of little bands, soaked in collodion, stretching to the forehead and the cheek. At the end of eight days all was healed; and, although the diameter of the palpebral aperture had only become enlarged by a line, that, combined with the section of the muscle, sufficed for the relief of the entropion. The patient was seen two months afterwards, and the cure was found to be a complete one. The operation was then performed on the other eye, and with the same success.

This case shows the necessity of exactly ascertaining the cause that gives rise to and maintains an entropion, before resorting to an operation, as, without this precaution, the ordinary procedure of removing some of the skin and application of a suture may do harm instead of good. In fact, such an operation exerts no influence on the spasmodic contraction of the orbicularis, while it diminishes the extent of the palpebral covering; so that, if care be not taken, a true ocular phymosis, aggravating the entropion, and impeding better devised operations, may be produced. It is not meant to be stated that this procedure is altogether new; for Wardrop had already indicated the incision of the external ligament in this variety of entropion. The most important point, however, is the complete section of the most external fibres of the orbicularis; and if this object be not fulfilled, all will be in vain. —*Presse Belge*, 1857, No. 48.

## GENERAL CORRESPONDENCE.

### ON ANGINE COUENNEUSE (DIPHTHERITE), OR THE EPIDEMIC IN BOULOGNE.

LETTER FROM J. WHITEHEAD, M.D.

[To the Editor of the Medical Times and Gazette.]

SIR,—Seeing by your Journal that great interest is excited by the appearance of Diphtherite in England, I think that an account of a case which came under my own immediate care might be perhaps worthy of a place in your Journal. I will therefore relate its history and treatment from the commencement to its favourable termination, in hope that my Medical brethren may perhaps suggest a more successful treatment than has been adopted here.

The symptoms of this disease are very similar to those of croup, but without the well-known peculiar crowing sound, and instead of coming on gradually, and with a short dry cough, they come on very suddenly; the child being perfectly well, suddenly complains of a little sore throat, which increases rapidly until the difficulty of swallowing is perceived. It is generally at this late period that a Medical man is first

apprised of the sudden illness, and upon examining the inside of the mouth and throat, one or both tonsils are found much swollen and dripping with a thick opaque and offensive matter; the fauces are very red and dry, and the breath begins to smell very offensively. Sometimes the throat is swollen very much externally from ear to ear. This disease also bears a resemblance to laryngitis, but without the rigors at the commencement. Having given a brief sketch of the disease I will now endeavour to narrate my case. I cannot give the *post-mortem* appearance, as it is very difficult to obtain permission to make an examination.

Case.—May 12, 1856.—Having previously lost two children in the same house, on Monday, May 12, 1856, I was requested to visit at 9 a.m. a Mr. P., aged 18, a strong, robust, healthy, young man. Upon entering the house, I found all the family in a state of great anxiety, as they said they feared it was too late (knowing how suddenly the other two were attacked and carried off). I found the patient nearly, to all appearance, choking; complaining of great difficulty of swallowing even his spittle; outside of the throat much swollen, and very hard and hot, but not very tender to the touch; could put out his tongue only a very little way; it appeared very dry, brown, and furred; pulse 120, but very weak; bowels had not been open since Saturday, when he first felt a slight sore throat, and was prescribed for by a Medical gentleman.

I ordered fomentations of camomile flowers and poppy-heads to the throat, as warm as possible, and the following enema: *Ol. ricini* ʒiii., *saponis* ʒi., *aq. fervent.* Oj.; and I put into the mouth *hyd. submur. gr. iii.*, which was carried down with difficulty by the saliva; the feet to be put into a warm bath with a quarter of a pound of mustard, and a small piece of the following paste to be occasionally put into the mouth:—*℞. Boracis*, ʒj, *mel.* ʒi.

At 3 p.m. I visited my patient again: found the bowels acted slightly; throat less swollen, and he could open the mouth better; fauces greatly inflamed; pulse 100, small; tongue brown in the centre, moist at the edges and tip; great prostration and difficulty of breathing; he complains of *some* of suffocation, but not so much as this morning.

I ordered the mouth to be gargled with acetic acid and water, sweetened with coarse brown sugar, with a little cayenne pepper, and a large mustard plaster smeared with iodine to be applied to the throat externally.

6 p.m.—Found him decidedly better; complains of pain in the stomach, which is very hard and tense; great flow of mucus from the mouth; upon examining which, I found several pieces of false membrane, which when dry appeared like pieces of horn: directed that the following powder should be given immediately:—*℞. Calomel.* gr. iij., *pulv. Jacobi*, gr. iv., and two table-spoonfuls of castor oil every two hours until the bowels act freely; and the stomach to be rubbed with warm sweet oil. The powder was only retained about three-quarters of an hour, when a large quantity of a dark substance, resembling coffee-grounds mixed with bile, was rejected. After two hours the first dose of castor oil was given, which was also rejected with the bile liquid as before, only it was more green and offensive. After two hours the oil was repeated, and was kept down, and produced a copious stool of dark green, very offensive matter, very similar to that vomited; after another quarter of an hour a similar stool, but more green and slimy. In the course of an hour another stool, but yellow and sticky; smells bad.

10½ p.m.—Found him much better; tongue cleaner; pulse 84, weak; throat not so much swollen; respiration better, and he could open his mouth much wider; all pain of stomach gone; urine still very high-coloured, but more plentiful. To gargle the throat with the following frequently:—*℞. Boracis*, ʒi., *mel.* ʒi., *tr. myrrh.* ʒii., *aq. rose.* ʒij., *aq. destill.* ʒiv. Repeat the mustard plaster to throat, only with half linseed meal.

May 13th.—Found him better; tongue very dry and brown; pulse 104, rather small; very thirsty, continually asking for cold water, which he says he can swallow better than anything else; has been very restless all night, his breath smells very offensively. To take the following fever mixture, two table-spoonfuls every 3 or 4 hours: *℞. Liq. ammon. acet.* ʒi. *potass. nitrat.* ʒss. *spt. ether. nitrici* ʒiii. *tr. hyoscyam.* ʒj. *mist. camphor.* ad ʒvi.; apply the poppy-head and camomile fomentation as hot as he can bear it to

the throat, and to take calf's-foot jelly without wine frequently.

Visited him again in the evening; fever much less; has slept half an hour very quietly, but upon waking complains of suffocation, and great pain in swallowing anything cold; bowels open; tongue much cleaner; no thirst; pulse 84, quick and weak; skin hot and dry; countenance flushed. Upon examining the throat internally, I discovered a large piece of false membrane firmly adherent to the fauces, and I removed it by the aid of a pair of forceps with difficulty, affording immediate relief. I also removed two large pieces from the tonsils, after which I introduced a camel's-hair pencil, and touched the fauces with the following caustic: *R. Acid. muriat. ʒj. mel. rosæ, ʒij.* and ordered two table-spoonfuls of castor oil.

14th.—Found him much better; bowels been open once well; tongue brown in the centre; pulse 90, weak; the throat a little more inflamed; to be continually gargled with thick barley-water sweetened with honey; to take anything light in the way of nourishment. Complains of want of sleep, and says, as soon as he lies down to try to sleep that he immediately feels a sense of suffocation; he has eaten a little bread and milk sop to-day; cannot take the jelly cold. To take an ounce of the following mixture every six hours:—*R. Potass. chlor. ʒj. aq. ʒvi. M.*; and to use the following wash for the mouth:—*R. Potass. chlor. ʒss., mel. ʒss. aq. Oss.*

8 p.m.—Visited him again; appears much better; complains of want of sleep; pulse 82, weak; tongue clean at edges, but furred in centre; to take all the liquid food possible, and a little wine and water; has had a little refreshing sleep at intervals.

16th.—Was called to him at 9 a.m. Complains of being almost suffocated. Great weight in the chest, and has a small, tight, troublesome cough. Upon examining the throat, could perceive nothing particular. Gave him immediately five grains of tartar-emetie, followed by plentiful draughts of warm water. After ten minutes he vomited at least a quart, to all appearance of pure bile, which he says tastes very bitter. He now complains of not being able to breathe through the nostrils. Upon an examination, I found two large pieces of false membrane adhering firmly to the sides of the nose, which I removed with the forceps, after which he lost a considerable quantity of blood, which could not be easily stopped. I applied cold water and a bandage round the forehead, which was constantly kept wet, but all to no purpose. I then was obliged to plug the nose, and the bleeding stopped. His father complains that all night and to-day he will take no food, and says it is no use trying further, as he must die. I insisted upon my plans being still carried out, or I should immediately give up the case.

2 p.m.—Found him very restless. He attempted to leave the room several times; would go up stairs, and would not be kept in bed, nor take any nourishment. Tongue very brown, and furred; skin dry and hot; pulse 104, quick, but weak. He says his reason for taking no medicine nor nourishment, nor using the gargle, is because it pricks his throat. Complains of great noises in his ears. In fact, I consider all this produced from want of sleep. I therefore ordered him to take a quarter of a grain of morphia directly: also one grain of quinine, and to repeat it every three hours.

6 p.m.—Found he had slept well and easily for nearly two hours. Tongue cleaner; spirits much better; appears quite sensible. Slight perspiration on his skin, and he promises to take the nourishment and medicine as ordered. I ordered him a table-spoonful of brandy and water every hour.

19.—10 a.m. Much better. Had a pretty good night, takes more nourishment, and seems to enjoy it. Alter the dose of quinine to gr. ij. three times a-day, instead of gr. j. every three hours, with the addition of *tr. aurant. ʒij.*

8 p.m.—Much better. Tongue clean, pulse 80, skin moist, bowels open, no headache; and fancies he could eat meat or an egg.

20th.—Much better in all respects; slept very quietly about five hours in the night; tongue clean; bowels acted once; pulse 84. To take a little fish and good strong beef-tea, and to get up a little, and change the air of the bedroom.

22nd.—Still improving, but slowly; pulse 82; tongue cleaning; cannot yet swallow anything solid; to go on in exactly the same way.

24th. Still better; to continue the same.

28th.—Not so well; complains of dragging pain round the umbilicus; very restless; pulse 94, quick; tongue rather coated; bowels not been open for two days; great pain, and sensation of weight between the shoulders. To take the following powder directly:—*R. Hyd. submur. gr. iij. pulv. opii gr. ss.*; and two hours after, two table-spoonfuls of the following aperient mixture:—*R. Liq. rhei co. ʒss., ess. zingib. ʒj., magnes. sulph. ʒij., infus. caryoph. ʒv.*, to be repeated every three hours until the bowels act freely.

29th.—The medicine produced two copious stools after taking two doses, and he found great relief; says he thinks he could eat a mutton chop, but cannot masticate it; ordered his father to give him bread soaked in beef-gravy, also beef-tea and arrow-root, and bread and milk for tea and breakfast.

31st.—In all respects much better; can sit up for four hours in the course of the day, without being very much tired; sleeps pretty well at night.

June 3rd.—Improving much. Masticated a small piece of roast mutton, but could not swallow it, and drank a little mild ale; desired that he should go out a little in the air, and before going out to take a biscuit and a little wine, or calf's-foot jelly made with wine.

7th.—Found him much better, with good appetite, but could not yet swallow solids. Can sit up all day without fatigue. Sleeps well. Bowels open, tongue clear. To gargle the throat constantly with brandy and alum, and to have occasionally, by the aid of a goose quill, powdered oak bark blown into the throat.

12th.—Found him nearly well, with the exception that he could not speak plainly; and he says that in all his stools there appears the same sort of skin as he used to vomit, and that it usually burns him before he can pass a stool. Ordered him, prior to going to stool and after, to pass a piece of fresh lard up the rectum.

21st.—Have not seen the patient for now nearly a fortnight; but calling to-day, found that he had gone out for a few hours to work in a garden (he being a gardener). His mother says that all he complains of now is a slight difficulty in swallowing solids, and that she cannot understand what he says, as he always appears to talk through his nose. I told them that they must have patience, as he had had a very narrow escape, and that I had no doubt that most of the mucous membrane had sloughed away, and that it must be renewed before he could speak distinctly.

July 13.—The young man called on me to-day to thank me, and to say he is now quite recovered; but I perceive still a peculiarity in his speech. I examined the inside of the mouth, which is still a little inflamed; but he says he feels nothing of it. I advised his still gargling it with some good old brandy, pure, two or three times a day. This case has certainly proved an excellent one both for the treatment and for pointing out the true character of the disease. Unfortunately it generally attacks young children, who are not able to explain all their aches and pains, nor can they be made to take the necessary medicines, nor to use the gargles. It is treated here by continual emetics, cauterising the throat internally, castor oil, blisters, and leeches externally to the throat. Diet, principally light broth. Tracheotomy has been tried, but unfortunately, from the attack being so sudden, it ends fatally before many other remedies can be tried; its usual duration being from thirty to forty-eight hours. It appears to be exceedingly infectious, as in almost all houses where there were more than one child, all were attacked unless they were ordered immediately away, which is in general the Medical man's first advice.

If any of my Medical brethren, who may perhaps have witnessed similar cases, will give us their opinion as to the malady and treatment, it will be not only contributing a boon to the people who may unfortunately be attacked with this fearful disease, but also to their Medical friends here and elsewhere.

I am, &c. J. WHITEHEAD, M.D.

Boulogne.

AT the last meeting of the Medical department of the University of Maryland, held March 10, in the New Assembly Rooms, the honorary degree of Doctor in Medicine was conferred upon the distinguished English chemist, Sheridan Muspratt, Ph. D. F.R.S.E., of Liverpool, England.

## COUP DE SOLEIL.

LETTER FROM GEORGE MACKAY, M.D.

[To the Editor of the Medical Times and Gazette.]

SIR,—In the number of your Journal of the 19th December, 1857, there is a communication "On Coup de Soleil, its Causes and Treatment," by Dr. Beatson, Staff-surgeon, First Class. To prove that bloodletting in this disease, as a general rule, is most injudicious and injurious, the author alludes to the cases of two field-officers of the Madras army, which occurred on the 12th of April, 1852, the day the force destined for the capture of Rangoon landed from the fleet. One case was that of an artillery officer; the other that of Major G., Brigade-major of the Madras troops, both of which proved fatal. Dr. Beatson repudiates any wish on his part to reflect on the treatment employed in these cases. This I fully believe; still I think it would have been well had he made himself more fully acquainted with the facts connected with them, before bringing them thus publicly to the notice of the Profession; and as Major G— was my patient on the occasion alluded to, I must request the favour of your allowing me a small space in your columns for the few remarks I have to make on the subject.

I served throughout the Burmese campaign in 1852-53 in Medical charge of a Native Infantry Regiment which formed part of the First Madras Brigade. On the day to which Dr. Beatson alludes, an officer, dressed in staff uniform, who on inquiry I found was the brigade-major, passed me, making his way to the front, where firing was at the time going on. I was struck with his appearance and staggering walk, and on going up to him I requested that he would sit down under a bush, the only procurable shade. He was short, stout, and plethoric; his symptoms were those of excitement, face flushed, eyes suffused, pulse rapid and full. I remarked to my assistant that it seemed an exceptional case in which bleeding was indicated, but that still it must be employed with caution. An attempt was made to obtain blood from a vein in the right arm, but without effect, the vessel being so deeply embedded in adipose tissue; a vein was immediately opened in the left arm, and though the symptoms seemed still to indicate the propriety of withdrawing blood, I felt doubtful of the result, and consequently kept my finger on the pulse. Certainly not more than two ounces of thick dark coloured blood were with difficulty obtained, when the pulse beginning to fail, the arm was immediately tied up. Cold water was at the same time being poured from a height on his head, and diffusible stimulants were immediately given, but he soon became quite comatose. Just at this time the enemy unexpectedly appeared on our left, and my patient and myself were exposed to a heavy fire, after which I was called to see an officer of my own regiment, said to have been dangerously wounded. I was consequently obliged to leave Major G—; but requested my assistant to continue the treatment, till the means of conveyance for which I had sent should arrive, and by which he was to be taken to the Field Hospital. My assistant soon joined me, stating that Major G— continued much the same, and that he had sent him to the Hospital. I subsequently heard that he gradually sank and died soon after reaching the Hospital. I pass over the mistakes in Dr. Beatson's communication regarding this officer being attacked on reaching the 9th regiment, etc., as these are matters of little importance, further than that they show he was either misinformed at the time, or his memory on the subject has failed him. The above, however, is the true statement of the case, regarding which, Dr. Beatson, after alluding to the patient having been bled, says, "within, I believe, an hour, or at any rate an hour and a half *post*, if not *propter hoc*, he was dead."

In alluding to the cases which occurred in the 51st regiment, of which Dr. Beatson was then Surgeon, he mentions that of the serjeant-major, and says that the Medical officer who first saw him took a few ounces of blood. This case proved fatal; but with reference to his being bled, Dr. Beatson does not say *post*, if not *propter hoc*, he died. On the contrary, he approves of the treatment, and says he would have done the same himself. I think, therefore, it might have occurred to him that Major G—'s case was probably one of the same kind, (which it was,) and that although there was not much hope of a beneficial result, still like that of his serjeant major, it was one in which he himself would have

attempted to take a few ounces of blood. Further, had he known that the quantity of blood taken from my patient was little more than one ounce (certainly not so much as two ounces), I do not think he would have said *propter hoc*, he died.

The idea that bloodletting is, as a general rule, injudicious and injurious in coup de soleil, is by no means new, but is, I think, the general opinion of medical men in this country. It was strongly impressed on my mind twelve years ago, having at that time had an opportunity of examining the bodies of several European soldiers who had died from this disease. These cases were treated by bloodletting, etc., under the then prevailing idea of the apoplectic nature of the disease. And I was surprised at the absence of the usual post-mortem appearances of apoplexy, and the frequency with which I found the right side of the heart full of blood, and the lungs congested. The nervous system is primarily affected, and through it the action of the heart becomes diminished, local congestions take place, for the relief of which the application of leeches may be advisable, but even they must be cautiously employed, and they are seldom to be had when required in such cases. On the other hand, there is little doubt but that cases of coup de soleil do occur in which general bloodletting is advisable. And we must be cautious not to go into the opposite extreme. As to the case of Major O—, mentioned by Dr. Beatson, I can say nothing, not having seen the patient; but with reference to that of the Brigadier of artillery, I am inclined to think that the lancet was judiciously used; and the patient afterwards expressed to me the wonderful relief he felt from the bloodletting, which he certainly would not have done had his been an ordinary case, with the usual nervous depression.

I have seen many cases with symptoms in every respect identical with those of coup de soleil brought to Hospital during the night, the history of which has always been that the patient has undergone considerable fatigue in the sun during the day, dressed in his uniform (which is fit only for a temperate climate), has gone to bed feeling only, as he thought, fatigued, but in a few hours afterwards being heard to breathe heavily, an attempt was made to rouse him, when he was found in a comatose state. These are undoubted cases of depression, and might be prevented by a suitable uniform, as recommended by Staff-Surgeon Beatson, and by good barrack accommodation; the former would enable European soldiers to undergo exposure and fatigue with greater impunity, and the latter would enable them to rally from the effects of it. The cases alluded to above occurred at a hot station, where the atmosphere at night was even more oppressive than during the day; the barracks were badly constructed and badly ventilated; on returning to them, instead of rallying from the effects of exposure and fatigue, the hot confined atmosphere of the room, poisoned by the exhalations from the lungs of so many human beings, tended to increase the depression, and produce symptoms which at other times occur more suddenly under the direct influence of the primary exciting causes. In such quarters, European soldiers in India are even worse off than when on active service in the field.

The construction of proper barracks for European soldiers in this country is a matter worthy of the most serious consideration; and in selecting sites advantage ought, as much as possible, to be taken of the hill stations. There is, I believe, no greater mistake than that of supposing that European troops located on the plains in India become acclimated, and thus better able to endure exposure and fatigue when required for active service. Such might to some extent be the case, if it were possible to ensure among them regular habits, temperance, and the avoidance of undue exposure to the sun, and also to provide them with some suitable means of employment and recreation. The rule I feel sure will be found to be, that the more nearly European soldiers approach the standard of health, the better they will endure fatigue and exposure during service in the field; and the climate of the hill stations in this country will be found better adapted for preserving Europeans in health, than for restoring the health of those who have suffered in the low country. These stations are, therefore, better suited for the location of whole regiments than for Sanatoria.

I am, &amp;c.

# ON THE TREATMENT OF GLAUCOMA BY THE EVACUATION OF A PORTION OF VITREOUS HUMOUR.

LETTER FROM J. W. HULKE, Esq.

[To the Editor of the Medical Times and Gazette.]

SIR,—I have just read in your Journal of April 24, some remarks by Mr. Middlemore, on the treatment of glaucoma by evacuating a portion of the vitreous humour, a proceeding which this gentleman deems preferable to the iridectomy practised by Dr. A. von Graefe, because, he says, it is more easily performed, and involves less risk than the latter operation, while he believes it to be attended with equally satisfactory results.

The objections which Mr. Middlemore raises to iridectomy seem to be twofold; they are the difficulty in the performance, and the risk which the operation involves. I think it will be an easy matter to show that these objections are not insurmountable, and it is also not more difficult to demonstrate that the evacuation of the vitreous humour in the manner advised by Mr. Middlemore is impracticable in cases of true glaucoma, at least in those stages of the disease in which any improvement of sight can follow active surgical interference.

It is quite true that iridectomy is an operation which requires some care and dexterity on the part of the operator for its successful performance; but surely not more than most Surgeons possess. The chief danger to be apprehended in its execution is injury to the lens, and this is the more likely to happen on account of the diminished size of the anterior chamber; but this danger may be safely avoided by closely following the directions laid down in my paper "On the Surgical Treatment of Glaucoma," which appeared in your journal of 29th March, the chief points being to make the incision by a steady onward movement of the knife, without sawing, and to keep the flat of the blade accurately parallel to the front of the iris. The performance of the operation will be much facilitated by putting the patient under the influence of chloroform, a measure which places the eye most completely under the control of the Surgeon. But as there may be some persons who would not like to undertake the operation of iridectomy, to them I would recommend paracentesis of the anterior chamber as the next best plan of treatment; the chief objection to it being the temporary nature of the relief which it affords.

The aqueous humour may be evacuated with a broad needle, which should be made to pierce the cornea at its margin, and enter the anterior chamber obliquely, great care being taken not to direct the point of the instrument backwards, for fear of wounding the lens. It may be necessary to repeat this operation several times. Having shown the main danger in the performance of iridectomy may be avoided, I will briefly consider the subsequent risks which the operation involves; and here I have little doubt that most persons without experience of this operation in glaucoma, would dread the access of inflammation as the chief risk to be apprehended; indeed, prejudice would easily make us mistrustful of the beneficial effects of any operation performed upon an eye in a chronic painful state, the seat of a disordered circulation, and liable from time to time to fresh inflammatory attacks. Experience, however, which in these questions will alone lead us to the truth, has amply shown that we have very little to apprehend from inflammation after iridectomy in glaucoma. The operation may be safely undertaken in all stages of the disease, and the best results are obtained in the most acute cases, both as regards the relief of pain and the improvement of sight; and it is only in a few exceptional cases of the chronic form that there has not been the same speedy relief of pain. In these chronic cases we cannot expect the same degree of improvement of vision which we meet with in acute cases, because in chronic glaucoma the structural changes in the retina proceed, *pari passu*, with the gradual increase of pressure and the diminution of sight; but even in advanced stages of the disease, where all hope of sight is utterly lost, if the eye continues painful, the operation should be performed with the view of relieving the distress.

Let us now consider the operation which Mr. Middlemore would substitute for iridectomy. It consists in the evacuation of a portion of the vitreous humour, which is done not merely to relieve the tension of the globe, but "by the removal of a turbid fluid, to afford an opportunity for its

replacement by a new and more transparent secretion." This evacuation is to be performed by piercing the sclerotic with a fine-grooved needle. Now the practicability of this operation in glaucoma must evidently depend on the consistence of the vitreous humour in this disease. What, then, is the condition of the vitreous humour in glaucoma? In the MSS. of the Jacksonian Prize Essay on Diseases of the Eye, by Mr. Middlemore, in the Library of the Royal College of Surgeons, and in a "Treatise on Diseases of the Eye," by the same author, I find the following description of the morbid anatomy and pathology of this disease:—"All the symptoms of acute glaucoma may proceed from a primary inflammation of the hyaloid membrane alone, a membrane which the author describes as having a cellular arrangement. The septa secrete the fluid the cellules respectively contain; and when the quantity of this fluid is much increased, the septa are broken down by the increased pressure which under such circumstances they sustain. Inflammation of the hyaloid membrane leads to an increased secretion of this fluid, the cellules are at first distended, and secondly, broken down or absorbed. We are thus led to infer that the fluid which these cellules contained is set free into the vitreous space—in short, that the vitreous humour in acute glaucoma becomes fluid, the only condition in which it could be evacuated with a very fine grooved needle passed into it through the sclerotica in the manner recommended by Mr. Middlemore; and indeed this gentleman in one passage calls the vitreous humour a turbid fluid. When this turbid fluid has been removed, an opportunity is afforded for the substitution of a new and more transparent secretion, the source of which is rather obscure, when we remember that the author has already told us of the destruction of the secreting cellules; but even in this dilemma we are not wholly without resource; for we find a suggestion to replace the "turbid secretion by the injection of a quantity of clear luke-warm water." The result of this treatment I will leave to the conjectures of your readers.

But this fluid condition of the vitreous humour is not really present in glaucoma, except in the most advanced stage of those cases which end in general atrophy of the globe; on the contrary, in acute glaucoma the vitreous humour is remarkable for its great firmness.

In a paper on the Morbid Anatomy and Pathology of Glaucoma read before the Royal Medical and Chirurgical Society on the 12th January of this year (a), I described, at length, the condition in which I had uniformly found the vitreous humour in the dissections of several eyes affected with glaucoma made immediately after their removal during life. I will here only mention that the vitreous humour in all these cases had a most striking and remarkable firmness, a consistence much greater than it naturally possesses, and which would make it quite impracticable to evacuate this humour along a fine grooved needle, as Mr. Middlemore advises. In proof of this assertion I will make the following brief extract from the paper just referred to:—

"With a view to relieve the tension of the globe, I have seen the sclerotic freely punctured with an extraction knife, after which firm counter-pressure with the finger upon the opposite side of the globe only caused the protrusion of a very small bead of yellowish vitreous humour, such great firmness had it."

It is obvious that with this condition of the vitreous humour, Mr. Middlemore's plan of treatment is impracticable, and therefore cannot replace the operation of iridectomy in these cases.

I am, &c.

J. W. HULKE.

King's College, May 8, 1858.

**PUBLIC HEALTH BILL.**—A Bill has been brought in by Mr. Adderley, M.P., and Mr. Secretary Walpole, for vesting in the Privy Council certain powers for the protection of the public health. The powers of the General Board of Health under the 18th and 19th of Victoria are added to those of the Privy Council. The Council is further empowered to order inquiries in matters relating to the public health, to appoint medical officers on the discontinuance of the Board of Health, and to issue rules for securing the due qualification of public vaccinators.

## REPORTS OF SOCIETIES.

## ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MAY 11, 1858.

Dr. J. A. WILSON in the Chair.

Mr. HOLMES COOTE read a paper on

## THE TREATMENT OF CONTRACTED JOINTS.

The author limited his remarks to contractions of the knee, as best illustrating this class of affections, and commenced by assuming certain propositions as granted—namely, that the diseases of joints may be generally classed under two heads—*struma* in the young, rheumatism or gout in the adult; that the morbid changes run through a definite course to cure; that the severer morbid changes, leading to the necessity of operation, are chiefly accidental—i.e. caused by inattention on the part of the patient or by improper treatment; that the flexed position of a limb is easiest to a patient during the acute stage of disease, owing to the relaxation of the ligaments; that the adhesions which form under these circumstances may be elongated or ruptured, but that the continuity of surrounding tendons should be preserved. The “pulpy thickening” of the synovial membrane, when it becomes converted into a light-brown-coloured mass, was regarded by the author as one stage in a progressive series of morbid changes, ending in the removal of articular cartilage. He regarded it as curable—i.e. as not necessarily leading to removal of the limb.

Rheumatic disease was also regarded as curable—that is to say, it pursues its course, and tends to changes which may be directed and greatly benefited by the aid of surgery. Bony ankylosis, rare in the former affection, is here by no means uncommon.

There are three methods by which a contracted limb may be straightened:—

1. Forcible extension, as practised by Dieffenbach and Louvrier.

2. Forcible extension following the subcutaneous division of tendons; the limb being flexed again until the divided parts have re-united, and the soft uniting medium is then slowly elongated.

3. The gradual extension of the uniting fibrous structure, either with or without the subcutaneous division of tendons.

The author illustrated his paper by cases, and concluded by strongly recommending the last-named proceeding.

Mr. FERGUSON said, the surgical aspect of the question only had been considered, and he presumed that the author did not desire any discussion on the constitutional treatment of the disease, taking it for granted that such treatment was always strictly attended to. In regard to the pathology of the disease the author had enumerated three classes, but he (Mr. Fergusson) should be disposed to set aside the “rheumatic” form, for although the Surgeon had much to do with it, it must be treated chiefly constitutionally. Amputation or resection might be occasionally required; but, as far as his experience went, such operations were extremely rare. He believed, with the author, that a very large number of cases of diseased joints were curable (or rather that they would get well spontaneously), but there was no novelty in that view. The Surgeon was often induced to recommend an operation from the occurrence of a crisis, the patient being in a hectic fever with the pulse at 130, and apparently sinking into the grave; and in a day or two after the operation it might be found that the pulse had fallen to 90. Yet even in those cases, where great alarm had been felt, the Surgeon might possibly have interfered too soon, not having courage to wait until the crisis had passed away, and those favourable changes occurred to which reference had been made. While, however, entertaining a strong opinion that in the course of time such diseases would, if judiciously watched, often get well, he felt equally sure that in a considerable number of cases some more active interference was necessary, and that instead of waiting it was better for the Surgeon to interfere. On such an important point the profession would not be satisfied with what the author had brought forward in order to show

that there was no need either for resection or amputation. No doubt he could adduce many more cases than he had related, but not all the cases occurring in the experience of any single individual would be sufficient to decide a question of so much interest and importance. The author stated that bony ankylosis was of rare occurrence. No doubt it was thought to be more common than it really was; but hundreds and thousands of cases might be seen in the museums and private collections. It was stated, and he concurred in the assertion, cases of bony ankylosis could not be interfered with in the way described; but the author had not referred to the state of modern surgery on that subject. Up to a recent date, ankylosis was considered the best result that could follow a joint-disease of the most formidable kind. No doubt it was so in many cases, but (as shown by modern surgery) not in all. After disease or resection of the elbow-joint, for instance, ankylosis was entirely set aside as the best result; and even where there was a stiff joint, the result of a cure by nature, it was a question whether the Surgeon was not justified in cutting down and making a new joint.

Mr. CURLING said, that those who had any considerable Hospital experience must admit the occurrence of cases of diseased knee-joint, in which it was impossible to save the life of a patient without an operation; and he believed that the modern plan of excision had often been adopted with great advantage, having the effect of preserving useful limbs. Cases taken to Hospitals had often proved to have been most seriously neglected, and the patients were sometimes so excessively reduced, that nothing but an operation could be of any avail. He did not believe that such cases presented themselves at Orthopedic Hospitals, which were regarded as places for the cure of deformity rather than of disease. He failed to discover any novelty in the system recommended by Mr. Coote, who, he thought, had taken a too unfavourable view of modern surgery. Surgeons were not so ready to condemn limbs as the author seemed to imply; and they frequently resorted to the remedial methods recommended in the paper.

Mr. CHARLES HAWKINS said, he had seen very many cases treated in the way described. With regard to resection, he did not think the necessity for it arose so frequently as many persons appeared to imagine. At any rate, according to his experience, legs were not amputated so frequently in former times as joints were resected now. Chloroform, with its many blessings, had brought with it some attendant evils, one of which was that operations were now more readily suggested and submitted to than formerly. He had seen a case in which a lady, residing at Edinburgh, was recommended five years ago to have a diseased limb removed, but her health was such that she could not undergo the operation. She afterwards came to London, and was advised by a leading Surgeon to submit to amputation, but her Physicians were of opinion that she could not bear it. The operation was never performed, and the lady was now cured, having as good a joint as any he had ever seen from resection.

Mr. BRODHURST said, he had never seen cases of partial ankylosis overcome by gradual extension, nor did he believe such an occurrence possible. He had seen cases of thickening of the synovial membrane where some contraction of the muscle had taken place, and where tendons had to be divided, the limb being thus restored; but he had never seen cases of partial ankylosis overcome, and motion restored without the adhesions being ruptured. He spoke with some degree of certainty on the subject, as he had had many cases of partial ankylosis under his care (some of which had been deemed incurable), in which he had ruptured the adhesions, and motion had been restored. In nineteen out of thirty-four cases partial and useful motion had been restored. Only the other day he had operated on a case in which motion had been perfectly restored. The patient, a young man, suffered from rheumatic inflammation, but within a month he was able to mount his horse, and ride twelve miles without pain.

Mr. HILTON thought that such a result negatived the conclusion that the disease in question was a very serious one, for he had yet to learn that a joint previously fixed by soft adhesion between the opposite surfaces, so that the patient was unable to move without pain, could recover in so short a period. The object of the author appeared to be to bring before the Society a class of cases, which, he thought, might be satisfactorily relieved by a comparatively trifling operation, in antagonism to a very general impression in certain sections of the Profes-

sion who were very much disposed to excise such joints. In that respect he (Mr. Hilton) agreed with him. Excision could not be considered free from danger; indeed, he believed when the statistics were collected from various sources, it would be found that that operation was really more dangerous than amputation. He did not agree with the author's statements that the pulpy degeneration, as described by Sir Benjamin Brodie, was a very common disease. The pulp-like granulations growing upon granulating bones were, no doubt, of common occurrence, and such joints often recovered by rest; but the disease described by Sir Benjamin Brodie was of a different character, and, he believed, of very rare occurrence. He did not concur in Mr. Fergusson's statement as to the great frequency of ankylosed joints.

Mr. SPENCER SMITH said he had never met with any one who had the hardhood to state that the pulpy degeneration of the synovial membrane was a curable disease; and he believed that in the case mentioned by the author, either the disease was not pulpy degeneration, or that the patient was not cured.

Mr. HOLMES COOTE briefly replied, and the Society adjourned.

## ROYAL INSTITUTION.

In Dr. Lankester's third lecture on "Plants as a Source of Food to Man," the inorganic constituents of food were farther investigated. Chlorine in combination with sodium had a remarkable influence on vegetable and animal life. The existence of the whole class of sea-weeds and sea-animals was determined by the presence of chloride of sodium (common salt) in the water in which they lived; sea-shore plants also required chloride of sodium. As we passed away from the sea-shore the chloride of sodium disappeared, and salts of potassium presented themselves in the tissues of plants and animals. Salt was, however, required by land animals, horses, sheep, and cattle, improved by the addition of small quantities to their diet, and man himself required a certain quantity to secure health. Its action was obscure, but its beneficial influence was undoubted. It was the only solid mineral food necessarily partaken of by man. Chlorine exists in the gastric acid, but whether as a chloride or hydrochloric acid is doubtful. Iodine was found in sea-weeds and sea-animals; and perhaps thus entered into the human system. It was stated to exist in water-cresses, but the lecturer had not succeeded in obtaining indications of the presence of iodine in London water-cresses. He suggested that the iodine was present in those water-cresses obtained from districts to which sea-water had access now or formerly. Silicon was shown to be present in many plants, and in the enamel of the teeth. The principal metallic elements found in the blood and tissues, and obtained from plants, were sodium, potassium, calcium, and iron. Sodium was mentioned under chlorine. Potassium was of interest in connexion with the production of scurvy. Dr. Garrod had shown that the diet which most favoured scurvy was deficient in potassa, while the vegetable substances, as oranges, lemons, water-cresses, cabbages, potatoes, etc., which cured it, contained potassa. A diet deficient in substances containing potash might lead to serious derangements of the system short of scurvy. Calcium had been mentioned in connexion with phosphorus, forming phosphate of lime. It also occurred in the human body, in the form of carbonate of lime. Although this substance occurred in hard water, it was found in the bones of people who drank soft water, and was undoubtedly carried into the system through the agency of plants. Another, salt of lime, found normally in plants, and abnormally in the human system, was oxalate of lime. Sulphate of lime is found in the pancreatic juice. Iron was an important constituent of the human blood. It was found in the blood of all animals. The ashes from a quart of ox blood were exhibited, and contained enough iron to affect the magnet. The human body contained from 80 to 100 grains of iron. When this substance was deficient, disease ensued, which was removed by the administration of iron, not in infinitesimal doses, but in doses sufficient to supply what was needed by the system. Iron is found in small quantities in the ashes of many plants, and generally in animals. The animals obtain the iron from plants. Magnesium is found in the tissues of

the animal body, in the form of a phosphate of magnesia, and the phosphate of magnesia, and ammonia. It is also found in some plants, and is probably thus supplied to the human system. Alumina, manganese, and copper are probably accidental constituents of the human body, when found there. In London, there is no difficulty in accounting for alumina in the body, as it is introduced by the adulteration of London bread. Copper and manganese, like many metals given as medicines, as zinc, bismuth, etc., supplemented iron, and acted on the system in the same way.

The next group of substances were called carbonaceous. They contained carbon in two relations, in one combined with oxygen and hydrogen in the proportion in which the latter formed water, as  $C_{12}H_{10}O_{10}$ ; in the other the oxygen was deficient, and carbon and hydrogen preponderated, as in the formula  $C_{11}H_{10}O$ . The first group contained starches and sugars, the latter oily matters. Starch and cane sugar must be converted into glucose or grape sugar before they are absorbed into the blood. Even cellulose could be converted into glucose in the human stomach. If the cellulose was dense, as in carrots, turnips, cabbages, it was not digested. Starch was readily converted into glucose, by salivine, pepsine, and other animal ferments. Starch existed almost pure in sago, tapioca, and arrow-root. It existed in large quantities in rice and the potato. The following analyses of these two articles of diet by Dr. Playfair were exhibited:—

RICE.		POTATO.	
In one pound.		In one pound.	
	ozs.		ozs.
Water . . . . .	2½	Water . . . . .	12
Gluten . . . . .	1	Gluten and Albu- men . . . . .	½
Starch . . . . .	11½	Starch . . . . .	2½
Sugar . . . . .	⅞	Sugar . . . . .	½
Gum . . . . .	½	Gum . . . . .	⅞
Fat or oil . . . . .	½	Fat or oil . . . . .	1½
Cellulose . . . . .	½	Cellulose . . . . .	½
Ashes . . . . .	⅞	Ashes . . . . .	½

Both these articles of diet were rich in starch, but deficient in proteinaceous matters. They were, therefore, bad substantive articles of diet, but valuable accessories.

## EPIDEMIOLOGICAL SOCIETY.

MONDAY, MAY 3, 1858.

Dr. BABINGTON, President, in the Chair.

A paper was read by Dr. W. CAMPS on

### EPIDEMIC DIPHTHERITIS AND PREVALENT SORE-THROAT.

The author commenced by referring to a paper on the same subject which he had read at the beginning of the year at the Medical Society of London, and then proceeded to state that since that time, the subject of diphtheritis in general, whether occurring in sporadic cases, or as an epidemic disease, has obtained increasing interest in the estimation of the Profession, and has attracted the attention of many observers, as well in the metropolis as in various parts of the country. The weekly mortality tables of the Registrar-General, the discussions upon the subject at some of the metropolitan Medical Societies, and the numerous communications made to our various Medical periodicals, some of which, in his judgment, are of great value; all these are evidence that the lately prevailing throat disease or diseases, by whatever name designated, have had directed to them no inconsiderable share of professional attention. His own attention to the subject had kept pace with that of his confrères, and he thought that on fairly and carefully submitting to the Society the facts that had come to his knowledge from various sources, bearing upon these prevailing affections of the throat, the members of the Society present would, with himself, come to the conclusion, that not only had throat affections been very prevalent of late, but, moreover, that in these might be recognised at least three well-marked varieties of disease, if not decidedly distinct diseases, indicated by well-marked and characteristic distinctions. In the first place, among these cases of so-called diphtheritis, diphtheria, or

prevalent throat disease, there have been not a few that have presented such characters as fairly entitle them to be considered as analogous to, if not identical with, that affection that has been so ably investigated and so well described by M. Bretonneau and others in France, and by him designated "diphtherite." In the second place, among these cases of so-called diphtherite, or diphtheritis, have been many that presented many of the characters of that affection of the throat, so well described in the last century by the eminent Dr. Fothergill, under the name "putrid sore-throat," or sore-throat attended with ulcers. In the third place, among these cases of throat affections lately prevalent among us, some must be allowed to have been that peculiar affection of the throat that accompanies scarlatina, whether the commonly attendant rash or eruption on the skin may not have been obscured, or in some cases even may not have been present. Admitting, then, the existence and prevalence of the above-mentioned forms of throat affections, the author contended that among these there had been cases in all variety, ranging from the mildest to the severest cases of one or other of these affections; and in order that his hearers might if possible know what nature says on the subject, instead of relying upon whatever he may think, Dr. Camps detailed in brief what he had been able to collect from all those observers who had taken the trouble to record their observations of the prevalent throat affections in various parts of the kingdom. He referred to the details of the disease that has been so fully investigated and described by M. Bretonneau in France, and to which he applied the term diphtherite. This peculiar disease has usually, though not always, appeared as an epidemic affection, some cases occurring sporadically, whether in France, or in this country. He thought that many of the cases of throat disease that occurred in 1855 and 1856 at Boulogne, were cases of diphtherite. Here it assumed quite an epidemic character, and in many instances it proved fatal to those attacked by it. In this country too, in the majority of the severer and fatal cases that had come to the author's knowledge, such had occurred in tolerably rapid succession as to time, and in tolerably close proximity as to place, many of them having occurred in subjects residing in the same house, others in the same village, town, or immediate vicinity thereto. The type of the disease, as described by various observers, is essentially asthenic, or adynamic; and therefore attended with more or less languor, depression, or impairment or diminution of vitality, thus indicating most clearly the appropriate mode of general treatment. Dr. Camps referred to the prevalence of stomatitis in some of the Metropolitan districts, between which disease and diphtherite, he thought the difference that existed was one of degree rather than of kind, the former affection being, as he considered, a milder result of the same general morbid cause. These varieties of subacute or asthenic mucous inflammations, attended with pseudo-membranous exudations of a fibrinous character, he regarded as so many different manifestations of the same general morbid conditions of the system; and this tendency to the formation of fibrinous pseudo-membranous exudations should be regarded as evidence rather of peculiarity than of intensity of inflammatory action. Dr. Camps referred to the recorded experience of Mr. Brown, of Haverfordwest, who, in 1849 and 1850, saw a great deal of a disease which he describes as diphtherite in that place, where it occurred as an epidemic, he having had under his own care at least two hundred cases, forty of which proved fatal. He detailed Mr. Brown's observations and treatment of the disease, as recorded by that gentleman in the *Medical Times and Gazette*, soon after the subsidence of the disease in that part of England. During that time Mr. Brown had the opportunity of making a post-mortem examination in two of his cases, in which the pharynx, tonsils, larynx, trachea, and bronchial tubes were found to be more or less coated with false membrane; the larynx and trachea were highly coated, and the stomach showed signs of great irritation also. In 1856 and 1857 an epidemic disease of a somewhat similar nature prevailed in two or three of the parishes of the Ely Union, in Cambridgeshire, in the practice of Mr. Davie, of Haddenham, who applies to the disease the term "broncho-tracheitis." This gentleman had about forty cases under his observation, of which more than one half, or upwards of twenty, proved fatal to those attacked thereby; and nearly all, if not all, of the sufferers were, as in Mr. Brown's cases, very young children; and in these the disease was of very short duration, existing in some instances only one day, and so on, varying in dura-

tion from one to four, five, six, or seven days. Mr. Davie made post-mortem examinations in three instances, and found the mucous membrane of the trachea and commencement of right bronchus inflamed to a small extent, the latter partly filled with fluid mucus. The left bronchus healthy, as also were the heart and lungs. In one case he perceived three distinct deposits on the mucous membrane of the trachea, somewhat resembling curd. The symptoms of broncho-tracheitis he considers to be widely different from those of laryngitis. From the description of diphtherite given by M. Trousseau, he considers the disease that came under his notice to be different from that; but, at the same time, he had two or three cases that he considered to be cases of the disease we now read of so frequently, and understood as diphtherite. One of these he saw in consultation with Dr. Fisher, of Cambridge, who, according to Mr. Davie, pronounced it to be one of diphtherite. The author of the paper then proceeded to consider the description of the putrid or ulcerated sore-throat, as detailed by Dr. Fothergill in his classical essay on this disease as it occurred in this country more than a century ago. This disease had not before that time attracted much attention in England, although it had spread like a plague through many of the southern parts of Europe about a century before, and had carried off great numbers of people, of young children especially. Dr. Camps read to the meeting the propositions laid down by the eminent Dr. Fothergill, in reference to the characters, progress, and termination of the prevailing or epidemic sore-throat of his day, as recorded in his valuable treatise on that subject, pointing out in what manner, in many respects, the description of that disease there given by Dr. Fothergill accorded with the description given of many cases of throat affection that had lately been brought under his own observation in his own practice, and in that of other practitioners, as well as of many cases recorded from time to time in our various Medical periodicals, or referred to in the various discussions upon diphtherite and throat affections that had lately arisen at Medical Societies. Dr. Camps then drew attention to a very valuable contribution to Medical literature, relating to diphtherite, by Mr. West, published in the last number of the *Midland Counties Journal*, wherein the subject was very fully discussed, at the same time stating, that in some respects he differed from the author of that paper. He then drew attention to the numerous communications on diphtherite and throat affections, that had appeared in the *Medical Times and Gazette* and other Medical Journals within the last twelve months, from numerous observers in various parts of the country, specifying particularly such instances as appeared to him to have been either true cases of diphtherite or ulcerated sore-throat, resembling that described by Dr. Fothergill, or sore-throat, accompanied by, or consequent upon scarlatina. He then commented upon the local reports upon the progress of epidemic diseases, recorded in Dr. Richardson's Sanitary Review, during the last six months, so far as these related to diphtherite and prevalent sore-throat, many of which included observations upon these affections which he thought of great value. He also drew attention to the records of fatal cases of diphtheria that had appeared of late in the weekly mortality tables of the metropolis, considering this term as denoting the same affection which has heretofore been described by observers under the terms diphtherite or diphtheritis. Dr. Camps concluded his paper by stating that from all the foregoing particulars it was evident that within the last twelve months or even less, throat affections of a more or less severe description have been very prevalent in many parts of England, whatever these may have been, or however they may have been considered in their special and general pathological characters, or however they may have been described and designated by their respective observers; and, moreover, he thought the facts that he had thus imperfectly put together, warranted the conclusions that he had drawn from them, and which at the beginning of his paper he had laid before the meeting. After the reading of Dr. Camps' paper a discussion followed, in which Mr. Lord, Dr. Greenhow, Dr. James Bird, Mr. Radcliffe, Dr. H. Webber, Dr. Milroy, and the President, Dr. Babington, took part.

APPOINTMENT.—Robert H. Moore, F.R.C.S.I., to be dentist to the Lord Lieutenant of Ireland.

## HARVEIAN SOCIETY OF LONDON.

THURSDAY, APRIL 15, 1858.

DR. HAMILTON ROSE, President, in the Chair.

Dr. B. SANDERSON introduced the subject of "Diphtherite" for discussion. There was much difference of opinion in the Profession as to the identity of diphtherite. He would first relate the symptoms of the disease described by M. Bretonneau, of Tours, then refer to the character of the disease which has recently been prevalent in this country, and finally compare and contrast them. Diphtherite was prevalent in America (where it proved fatal to Washington), and other countries, before it was described by Bretonneau. It was not dependent on local causes or over-crowding; it was capable of transmission by personal contact, but not through the air. It resembled much our croup, differing in this respect, that the first appearance of the exudation was on the tonsils. The character of the exudation was very tenacious, and covered the whole of the pharynx, and not parts. The constitution was but little affected, and if the local disease could be relieved, that was all that was necessary. The disease recently prevalent in this country Dr. Sanderson believed was identical with the malignant sore-throat described by many authors, and that in a great number of instances scarlatina precedes it. There was fetid breath, much fever, amounting sometimes to a typhoid character. The thickness and adhesiveness of the exudation was less marked than that described as occurring at Tours, and the mode of death was different. In this country exhaustion and fever destroyed the patient, rather than the asphyxia, which suddenly put an end to Bretonneau's patients. In true diphtheria there was no fever and no fetid breath; both these were remarked in this country. In true diphtheria the local affection was all important, and rather of a chronic nature; the exudation was firm, elastic, and extremely tenacious. In this country the general symptoms were of more importance than the local, and the exudation was less firm and more easily broken up. Death occurs from asphyxia in the true disease, and from the constitutional affection in the recent prevalent attack. The treatment likewise indicated the wide difference between the two diseases. Here a tonic plan had been undoubtedly called for, while the true diphtherite was treated by antiphlogistics. The speaker concluded by asking, "Is there such a disease in England as M. Bretonneau describes?" and in the experience of members, "Was a strong or a weak solution of caustic the most useful as a topical application?"

Mr. STEWART related some cases bearing upon the subject, and said that in one case there was considerable œdema of the neck, with enlargement of the submaxillary glands. In one case only had he seen the granular deposition, and the exudation in all the other cases was thick mucus.

Mr. CLEVELAND had seen lately many cases of severe sore-throat, but in none was there a false membrane, and therefore he considered that the true diphtheria was a very rare disease in this country.

Dr. HUTCHINSON POWELL agreed with Dr. Sanderson, that the disease lately prevailing was a distinct disease from that described by Bretonneau. Dr. P. in his practice had seen much sore-throat, of a low character, with œdema glottidis and swelled glands. The best treatment he found was dilute nitric acid locally, and tonic treatment internally. He differed from Dr. S. in the opinion that local circumstances had no influence in producing the disease.

Mr. LOBB had suffered himself from fever, delirium, and sore-throat after attending a child with scarlet fever. The throat was swelled to such an extent that he could not swallow for several days, a mucous exudation ensued, and then hæmaturia, and he got well. He had seen many cases since, and had used the solid nitrate of silver with advantage.

Dr. WEBER had seen these cases in London, and had not remarked the swelling of the throat or the fetid breath. He had applied a strong solution of nitrate of silver, and had obtained fungoid casts thrown off from the throat. A child, under Dr. Barlow's care, in Guy's Hospital, had swelling of the throat for three weeks, with symptoms of croup. It died, and the false membrane extended from the larynx into the pharynx. Five other children in the same family were attacked, and all had caustic applied. A country gentleman

had his throat covered with grey patches; there was no swelling. He died from exhaustion.

Dr. CAMPS considered that there were different affections of the throat described under one name, but that there were nevertheless real cases of diphtherite in this country. At a place in the country an epidemic of what was called croup, but which the Medical attendant said differed somewhat from the usual character of that disease, occurred. The rare circumstance of an epidemic of croup led Dr. Camps to the opinion that this outbreak was, in fact, the disease under discussion. He believed that cases began as diphtherite, and ran afterwards into croup, and so we get a complication which mystifies the diagnosis. The prevalence of stomatitis of late, indicated to his mind a diphtheritic tendency. He eulogised the treatment by solid nitrate of silver applied locally, and strong supporting food and medicines. In some cases emetics and calomel might be used advantageously.

Mr. EARDLEY had seen a case of diphtherite in which the pharynx was covered with a grey deposit. Antiphlogistic treatment, with solution of nitrate of silver locally, had no influence over the disease. Subsequently strong hydrochloric acid was applied, which removed some of the fibrinous deposit. Port-wine and beef-tea were freely administered, and poultices applied externally. This treatment relieved all the symptoms, and much of the exudation was spat out, looking like semi-liquid glue. This child perfectly recovered. A young man, aged 20, had a white granular deposit on the tonsils, which was likewise removed by hydrochloric acid, causing the expulsion of a fibrinous cast.

Dr. POLLOCK believed that Bretonneau had painted his disease in a manner which would not compare with the reality. True diphtherite, so described, was not a prevalent disease; but many cases more or less approximated to it. Definitions in medicine confined our notions, and cramped our practice. All these cases arose from a poisonous influence, and, however different, were yet identical. He had remarked in the same family how these throat affections approximated and diverged from the diphtheritic type: in some there was exudation, in others ulceration and excavation. He found strong caustics the most beneficial application, and the internal use of calomel generally desirable.

Dr. SANDERSON, in reply, said that diphtherite and croup were one and the same disease, and that, in his opinion, the pultaceous pharyngitis of the French was the disease lately prevalent in this country.

The Society then adjourned.

## NORWICH PATHOLOGICAL SOCIETY.

DR. WM. WOODHAM WEBB, President.

DR. RANKING read a paper on

## FUNGUS HEMATODES OF THE LIVER, MESENTERIC, AND OTHER ABSORBENT GLANDS.

The subject of this case was a man aged 30, a patient of the Norfolk and Norwich Hospital. The chief symptom was severe paroxysmal pain near the umbilicus, which could be controlled only by opium. He had the aspect of serious organic disease, but no tumour could be felt; his digestive functions were performed in a healthy manner, his respiration was good, the heart's action regular, and there was no evidence of hepatic disturbance. He left the Hospital unrelieved, and was re-admitted soon after, in a much emaciated state, with a sallow anxious countenance. The pain (as before) was paroxysmal; and being accompanied by retraction of the Testicle, was thought to depend on renal calculus. After a few weeks, vomiting became an urgent symptom, jaundice followed, the original pain continued, and he died. The lungs and heart were found healthy. The liver was converted into a mass of fungoid cancer. The mesenteric and cervical glands were of the same morbid structure. Kidneys healthy.

G. W. W. FINTH, Esq., related a case of

## MALIGNANT DISEASE OF THE STOMACH AND DUODENUM.

The patient from whom this specimen was taken was an inmate of the Norfolk County Asylum, on account of epilepsy and dementia. He was suddenly attacked with faint-

ness and copious hæmorrhage from the bowels, followed by vomiting of blood, symptoms which soon proved fatal. On examination small scirrhous tubercles were found beneath the peritoneal coverings of the stomach, and two oval tumours between the peritoneal folds of the duodenum and jejunum, in both of which softening had commenced, and had led to the hæmorrhage.

G. W. W. FIRTH, Esq., related a case of

#### RESECTION OF KNEE-JOINT.

The patient was a lad aged 13, in the Norfolk and Norwich Hospital. Six months before admission he punctured the joint with a thorn; destructive inflammation ensued, and on admission the knee-joint was almost immovable, bent nearly to a right angle, and the tibia was partially displaced backwards. There was considerable enlargement of the whole joint, due rather to bony expansion, than to synovial thickening. The operation was performed by making a semilunar incision, and turning up the patella in the flap. When the ends of the bones were removed to a sufficient extent, the limb was properly adjusted, and placed in a wooden box, so contrived, that in all future dressings the limb was not moved. Recovery was quick and perfect, and the boy (who was introduced to the Society) is able to walk with but little lameness. The cartilages were found not ulcerated, but at various parts they were yellow, softened and separated from the bone beneath.

W. CADGE, Esq., related a case of

#### LOOSE CARTILAGE FROM THE KNEE-JOINT.

A man, aged 74, was admitted into the Norfolk and Norwich Hospital on account of lameness, consequent on the presence of a loose cartilage in the left knee. He injured the joint in a fall, about eighteen months previous to his admission, and soon afterwards became aware of something unusual and moveable in the joint. There was not much swelling, and no heat about the knee; the foreign body could be felt, sometimes at the upper and outer, and sometimes at the upper and inner part of the synovial capsule. It could be easily pushed from one part to the other, but its size apparently prevented it from getting between the ends of the bones. It was fixed at the upper and outer angle of the joint, and the capsule opened by a subcutaneous incision. It was intended that the plan recommended by Goyrand and Syme should be carried out; but the great size of the foreign body made it difficult to provide a resting-place fairly outside the synovial capsule. It was therefore cut upon to a sufficient extent, and removed at once. No inflammation followed, and the man was discharged cured. The foreign body was oval in shape, and flattened; it weighed two drachms and a half, and was composed, its outer portion of glistening cartilage, and its centre of bone.

T. W. CROSSE, Esq., related a case of

#### PATHOLOGICAL APPEARANCES, FOURTEEN YEARS AFTER THE REMOVAL, BY LIGATURE, OF AN INVERTED UTERUS.

The specimen was taken from a woman, whose uterus had been removed by ligature by the late Mr. Crosse, in consequence of its having become inverted after labour. On January 14, 1843, she was delivered of a living child, and profuse hæmorrhage ensued, owing to an adherent condition of the placenta, which had to be removed piecemeal. It was necessary to pass the catheter thirty-six hours afterwards, no urine having been passed, and in doing so, a large body as big as the fist was felt in the vagina, and recognised to be the uterus completely inverted. Every attempt was made both then and subsequently, to replace it, but without success, and on the 12th February a ligature was placed on the neck of the uterus, which by means of an instrument could be tightened or loosened at pleasure. Five days afterwards the tumour having become flaccid, dark and putridified, it was cut off three quarters of an inch below the ligature to the great comfort of the patient. At the expiration of twelve days the ligature was removed, and the small remaining slough left to separate spontaneously. By the 20th March she was restored to as good health as usual. In Aug. 1849, she suffered an attack of profuse hæmorrhage, which was checked by the internal administration of ergot, and plugging the vagina. In 1856 she became an inmate of the Norwich Bethel, having become despondent and melancholic, and

possessed of many delusions. From this place she was discharged cured at the expiration of six months, but she suffered a relapse the year following, and in October, 1857, destroyed herself by hanging. At a post-mortem examination the ovaries were found to be of natural size, occupying a central position, and lying almost side by side in the cavity of the pelvis. They had their usual relation to the Fallopian tubes, which were similarly displaced, and found to be pervious for several inches. The vagina was perfectly healthy, and very capacious. The os uteri was normal in its situation, there were several abrasions of its surface; a probe could be passed in through it, to the extent of about one inch and a half. The remaining tissues did not appear to have undergone any other material alteration, either in position or structure.

### CONSULTATIONS WITH HOMŒOPATHIC QUACKS.

THE following important resolutions were passed at the meeting of the South Midland Branch of the British Medical Association, held on Friday, the 21st inst. :—

"1. That so long as a system has no higher philosophy than the jargon of 'similia similibus curantur,' nor sounder chemistry than the delusion of 'infinite dynamization,' it is degrading to a man of education to be connected with it. He, therefore, who assents to consultation with Homœopaths, be they impostors or dupes, forfeits the respect of his professional brethren, and his membership of this branch of the British Medical Association."

"2. That it is the opinion of this meeting that no honourable man, whether Physician or Surgeon, can meet in consultation a Homœopathic practitioner, or, as such, can act in conjunction with him."

### MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at the meeting of the Court of Examiners on the 10th inst. :—

DEOLIN, HENRY W., Green-hill, Ballygawley.  
EARLE, JAMES N., Brunswick-street, Trinity-square.  
HOLLINGS, ROBERT, Woodlesford, near Leeds.  
JACKSON, JOHN, Leicester.  
ORD, GEORGE R., Brixton-hill.  
WAIT, JOHN S., Bury, Lancashire.  
WALKER, HENRY, Malton, Yorks.

Also on the 21st :—

FAWSETT, FREDERICK, Wisbeach, Cambridgeshire.  
FLINN, JOHN JAMES, Liverpool.  
GRIFFITH, HUGH, Pwllheli, North Wales.  
HETT, HENRY NICHOLSON, Brigg, Lincolnshire.  
HOUSLEY, JOHN, Mansfield, Woodhouse, Notts.  
JONES, J. MORGAN, Rhydypererinion, South Wales.  
LAMBLY, THOMAS WALCOTT, Demerara, West Indies.  
LOMAS, WILLIAM, Guildford.  
MASON, FREDERICK JOHN, Wisbeach, Cambridgeshire.  
MORRIS, WILLIAM HENRY, Studley, Warwickshire.  
NISBETT, ROBERT INNES, King William-street, City.  
VINTRAS, ACHILLE, Tilly-sur-Seulles, Calvados, France.  
WALKER, ARTHUR, Scarcroft, near Leeds.  
WHITWORTH, JOHN, Heckmondwike, near Leeds.  
WOTTON, CHARLES, King's Langley, Herts.

Also on the 24th :—

CARDELL, GEORGE, St. Columb, Cornwall.  
CATZER, THOMAS, Erith, Kent.  
HILL, THOMAS JOHNSON, Melton Mowbray.  
IRWIN, JAMES, Sixmile-cross, Co. Tyrone.  
LAW, JOHN, Hon. East India Company's Service.  
MOXON, WALTER, Barnsbury-park, Islington.  
M'CARTHY, FLORENCE, Cork.  
PARTINGTON, GEORGE AUGUSTUS, Manchester.  
ROCHE, WILLIAM, Fermoy, Co. Cork.  
WILKINSON, JOHN, Salford.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, May 20, 1858:—

BELCHER, ROBERT SHIRLEY, Burton-on-Trent.  
 BENNETT, EDWARD AUGUSTUS, Manchester.  
 EDWARDES, CHARLES LAWRENCE, Pitsea, Essex.  
 GORDON, WILLIAM, Cradley, Dudley.  
 HUGHES, THOMAS HUNTER, Pwllheli, N. Wales.  
 JENNINGS, FREDERICK COOK, Wakefield.  
 JULATT, CHARLES JAMES, Manchester.  
 NAYLOR, JAMES, Halifax, Yorks.

**UNIVERSITY OF CAMBRIDGE.**—The following gentlemen have been examined and approved for the Licence ad practicum in Medicina:—

DUDLEY, J. G., M.A., St. John's College.  
 HAMILTON, R., M.A., Trinity College.  
 HODGKINSON, D. H., M.A., Trinity College.  
 INGRAM, C. P., M.B., Trinity College.

At the same time, A. RANSOME, B.A., Caius College, passed the examination for the degree of M.B.

#### DEATHS.

COULL.—May 22, at Ruthven, Mr. George Coull, Student of Medicine, aged 25.

COWE.—May 13, at Nethertown of Lomnay, Alexander Cowe, Esq., of Crimond, aged 67.

DUNCAN.—On the 13th March, at sea, on board the screw steamer Calcutta, from Bombay, Archibald Alexander Duncan, M.D., H.E.I.C.S., son of the late Mr. George Duncan of Edinburgh.

ON the occasion of the triennial visitation of Queen's College, Galway, held on Wednesday, May 19, the Right Honourable Maziere Brady, Vice-Chancellor of the Queen's University, having, among other inquiries asked if any of the students had any complaints to make, two of the Medical students made objections to the present mode of distributing prizes in the department of medicine and surgery; but the explanations of Dr. Croker King were satisfactory, and the Commissioners explained to them that any changes proposed to be made in the present system, should be brought first under the notice of the council, and then, if they were dissatisfied, the matter could be brought under the notice of that board.—*Saunders of May 21.*

**THE ARMY SANITARY COMMISSION.**—The 79th "Appendix" to the Report of the Commissioners appointed to inquire into the sanitary condition of the army has just been published in the form of a blue-book of 200 pages. It contains a variety of miscellaneous correspondence on incidental matters.

**PUBLIC PLAYGROUNDS.**—A Bill of Mr. Slaney, M.P., and Mr. Briscoe, M.P., enacts that any lands may be lawfully conveyed to trustees to be held by them as open public grounds for the resort and recreation of adults, and as playgrounds for children and youth, or for both purposes. No conveyance for this purpose need be stamped or enrolled. The first trustees for holding these grounds must be approved by the Charity Commissioners. The trustees will form a body corporate for the holding of such lands.

**THE OUTRAGES ON WOMEN IN INDIA.**—The question so much discussed in England, of the reality of the horrors of torture and mutilation said to have been perpetrated by the mutineers and rebels has been the subject of much discussion in India also. It is true that, though but few living examples of ladies or children who have suffered these cruelties have been seen by many in Calcutta, instances of the kind have not been wanting. But too much weight has been attached to the existence of living instances of cruel atrocity. The proof of the crime does not depend on that fact. Those unfortunate ladies who survived the horrors to which they had been subjected would be the last to come forward and bear unnecessary testimony against the mutineers, while the reason that so few are comparatively to be seen lies in the fact that in nearly all cases of personal violence to English women, torture, mutilation, and other outrages were the mere

cruel preludes to murder. Very few, once in the power of these Sepoy monsters, escaped with life to show in their own persons the proofs of the cruel sufferings they had undergone.

**SUCCESSFUL REMOVAL OF THE SCAPULA AT THE JERSEY HOSPITAL,** BY MR. G. M. JONES.—The entire scapula, along with an inch and a half of the clavicle, was removed on the 19th of May from a girl, aged 14, for carious disease of the entire bone. Only one vessel, the posterior scapula, was tied, and the patient, up to the present time (26th), is doing exceedingly well.

**HORSE-FLESH AS HUMAN FOOD.**—The *Journal de l'Ain* says:—"A dinner of horse-flesh has just taken place at Bourg, some amateurs having assembled at the Hotel du Midi for the purpose. Soup, cutlets, steaks, and roast joints were made from a fine animal which it had been found necessary to kill on the previous day. The guests did not, however, appear to be much delighted with the novelty. Notwithstanding all the care used in the preparation of the dishes, there still remained a certain flavour *sui generis* which affected delicate palates, and we think it will be long before the genuine beef will be supplanted by the flesh of the horse."

**THE VACANT CHEMISTRY CHAIR AT EDINBURGH.**—The patrons (Town Council of Edinburgh) have resolved to elect a Professor to fill this chair on the 29th of June. Professor Faraday has declined to accept the chair, even if offered to him, and Dr. George Wilson, Professor of Technology at Edinburgh, who would in all likelihood have carried the election on Dr. Faraday declining, has withdrawn his name from the list, the Government, to retain his services in his present chair, having augmented his salary. Since Professor Wilson's withdrawal Dr. Lyon Playfair has come into the field with considerable prospects of success. The attendance of all the students at the Chemistry Class being imperative, the chair is thereby rendered one of the most lucrative in the University.

**POISONING BY CIGARS.**—Professor Bunsen, of Heidelberg, has just started a question of interest to smokers, viz. the possibility of poisoning by introducing arsenic into a cigar. From various experiments made in his laboratory by Dr. Reising, it appears that the quantity of arsenic acid which may penetrate into the mouth is about a grain and a half, when the cigar has been steeped into a solution of arsenic; and that the quantity inhaled under the form of smoke is about one-eighth of a grain, when the cigar is filled with arsenic in its solid form. What has given rise to these investigations is a recent case of poisoning at Genoa.—*Galignani.*

His Excellency the Lord Lieutenant visited the House of Industry Hospitals in Dublin, last week, accompanied by Major Hamilton, Aid-de-Camp in waiting. His Excellency proceeded first to the Richmond Hospital, where he was received by the Governors of the House of Industry present, and accompanied by the Earl of Meath went through the several wards, the theatre and the museum, where he was shown the various objects of interest in the valuable collection which the latter contains. He next visited the Whitworth Hospital, and passed through the wards, remarkable for their cleanliness and comfort. His Excellency expressed the gratification which he felt at the various arrangements made for the accommodation of the inmates, and the regularity with which they are carried out under the direction of the Physicians who attend the Hospital. Among those present were the Earl of Meath, the Hon. R. G. Talbot, Captain Lindsay, Alderman Atkinson, Hans Hamilton Woods, Esq.; Dr. Corrigan, Surgeon Adams, and Surgeon Hutton, Governors of the House of Industry; the Venerable Archdeacon Gould, Dr. McDowell, Dr. Banks, and the Rev. T. A. Shore, chaplain. His Excellency was conducted through the grounds of the Hardwicke Fever Hospital, and left shortly after 4 o'clock.—*Saunders of May 21.*

**PUBLIC HEALTH IN RUSSIA DURING 1856.**—From the official documents just issued by the Minister of the Interior, we learn that the state of the public health in the entire Russian empire was in a more satisfactory condition during 1856 than it had been for some years previously. Of 359,853 persons seized with epidemic affections, 26,760 only died, being a number six times less than during 1855. The cholera, though still prevailing extensively, was milder, as there were but

14,744 cases, with 6282 deaths, i.e. 1 in 24, a prevalence twenty times less than in 1855. Of 78,505 typhus patients, 11,214 died—1 in 7; of variola, 1157 persons died, 1,222,175 children were vaccinated, and 366,281 remained unvaccinated. The Minister ordered these to be vaccinated as speedily as possible, and that revaccination should be performed in any locality where variola prevailed. The power of the virus forwarded to Kamtschatka in glass tubes was found to have been completely preserved. In the large towns rigid inspection of the working classes has been instituted for the detection of cases of syphilis, and only fifty-three such cases have been discovered among these classes in St. Petersburg, and 175 in Moscow. Nevertheless there were 37,916 persons treated for it in the civil hospitals of the empire. In spite of all precautionary regulations laid down by the Government, forty-seven cases of poisoning from salted fish occurred. In the 520 hospital establishments under the direction of the Minister, there were treated 403,630 persons, of whom 340,699 recovered, and 39,379 died. The following are the particulars of some of the affections:—Synochus, 100,739, died 1299; typhus, 78,505, died 11,214; intermittent fever, 95,668, died 720; dysentery, 19,121, died 2560; variola, 6266, died 1157; scarlatina, 4974, died 704; measles, 8063, died 757; pertussis, 5827, died 323; sudden deaths amounted to 15,264, and of these 200 were from poison, 810 from bodily injury, 1174 from asphyxia, and 1535 from excessive brandy-drinking.

## VITAL STATISTICS OF LONDON.

Week ending Saturday, May 22, 1858.

## BOOKS RECEIVED.

On Improving the Sanitary Condition of large Towns, by fossilizing and Deodorizing all the Sewage Matters of Dwelling houses, &c. By J. Lloyd, M.D.

Second Report of the Commissioners of her Majesty's Customs on the Customs. London: 1858.

Cosmos; Sketch of a Physical Description of the Universe. By Alexander von Humboldt. Vol. IV. part I. London: 1858.

Report of the Committee of Visitors of the Lunatic Asylum for the North and East Ridings of Yorkshire. York: 1858.

## TO CORRESPONDENTS.

Dr. Kramer's paper shall receive early attention, and will shortly be inserted.

The Report of the North London Medical Society will probably appear next week.

Dr. Maddock is thanked for the extract, but it appeared in our columns last week.

J. T.—Any respectable Surgeon can treat the diseases in question. It is contrary to our rule to recommend any practitioner in particular.

Mr. Augustus James.—The letter should have been directed to the Journal in which the remarks appeared. We do not open our columns to criticism upon communications made to other journals.

ERRATUM.—In Dr. Budd's paper on "Diabetes," which appeared in the "Medical Times and Gazette" of last Saturday, page 522, in the passage "in a daily gain of many thousand grains," for "many" read "nearly three."

B. A. Cantab.—To the best of our belief, a person who has taken only the licence *ad practicandum in Medicina*, of Cambridge, is not entitled to the name of Doctor; but so many titles are given by courtesy to those who have no right to them in law, that we find it difficult to give any authoritative opinion on the subject.

Crito.—The pretence that Homoeopathy is a system of Medicine, and that the Profession is divided into Homoeopaths and Allopathists is a mere blind to deceive the ignorant. Homoeopathy is not a system of Medicine at all, but a mere tissue of absurdities too ridiculous to be believed by any sane person.

Mr. H. H. Watson has forwarded to us a supplement to the *Witchamr* Herald, which contains letters from Dr. Alfred Taylor and Dr. Odling upon the real meaning of the term oil of vitriol. These distinguished chemists think that the latter term should indicate only sulphuric acid of the sp. gr. 1.845; and that the acid first obtained from the leaden chambers in the manufacture is not entitled to the appellation of oil. As we have before remarked, the term oil of vitriol is only a conventional one, because sulphuric acid is not an oil, nor is it obtained usually from sulphate of iron, or green vitriol.

COMMUNICATIONS have been received from—

DR. SEATON; MR. JOHN COVENTRY; THE SEWAGE COMMISSION; MR. REDFERN DAVIES; MEESRS. BEARD AND SHARP; THE GENERAL BOARD OF HEALTH; DR. J. W. GRIFFITH; I. T.; DR. SHERIDAN MUSPRATT; MR. G. M. ## APPOINTMENTS FOR THE WEEK.

May 29, Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m.; Charing-Cross, 1 p.m.  
MEDICAL SOCIETY OF LONDON, 8 p.m.: Mr. R. Barwell, "On Cystic Tumours occurring in the Neighbourhood of Joints."  
ROYAL INSTITUTION, 3 p.m.: Edwin Lankester, M.D., F.R.S., F.L.S., "On the Vegetable Kingdom in its Relations to the Life of Man."

31. Monday.

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.; Orthopaedic Hospital, 2 p.m.

June 1. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.  
ROYAL INSTITUTION, 3 p.m.: J. P. Lacaze, Esq., "On the History of Italy during the Middle Ages."

2. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Orthopaedic Hospital, 2 p.m.

3. Thursday.

Operations at St. George's, 1 p.m.; Middlesex, 12½ p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.  
CHEMICAL SOCIETY, 8 p.m.  
ZOOLOGICAL SOCIETY, 3 p.m.  
LINNEAN SOCIETY, 8 p.m.

4. Friday.

Operations at the Moorfields Ophthalmic, 10 a.m.; Westminster Ophthalmic, 1½ p.m.; Great Northern, 2 p.m.  
ROYAL INSTITUTION, 8½ p.m.: Professor Tyndall, "On the Mer de Glace."

## EXPECTED OPERATIONS.

St. Thomas's Hospital.—The following operations will take place this day (Saturday).  
Amputation of leg; excision of knee-joint; for ununited fracture; necrosis (two cases). By Mr. Solly. Necrosis of wrist. By Mr. South.

King's College Hospital.—The following operations will take place this day (Saturday), at 2 o'clock:—

Hare-lip; puncture of cyst by side of knee. By Mr. Ferguson. Removal of dead bone from foot. By Mr. Bowman. For the radical cure of hernia. By Mr. Wood.

## ORIGINAL COMMUNICATIONS.

## ON THE USE OF

METALLIC SUTURES AND METALLIC  
LIGATURES IN SURGICAL WOUNDS AND  
OPERATIONS.

By J. Y. SIMPSON, M.D.

Professor of Medicine and Midwifery in the University of Edinburgh;  
Physician-Accoucheur to the Queen in Scotland, etc. etc.PART I.—METALLIC AND OTHER THREADS IN SURGERY;  
THEIR HISTORY.

THE attention of the profession, particularly in America, has of late been strongly called to the value of metallic sutures, instead of organic sutures of silk, flax, etc., in stitching wounds. Taking, in the meantime, as granted, the advantages claimed for metallic sutures, on the score of being less irritating material than threads composed of animal or vegetable substance, I herewith venture on the same grounds to suggest, that the use of metallic ligatures to secure and tie the blood-vessels laid open in the sides and depths of wounds made in the course of surgical operations and injuries, is a matter of as great, if not greater, moment than the use of metallic sutures to close the outer lips of such wounds. In order, however, to explain the advantages which will, as it appears to me, probably be derived from metallic ligatures in surgery, it is necessary to consider, in the first instance, the advantages obtained by the employment of metallic sutures. And in doing so, I shall take leave to premise a few remarks on the materials out of which surgical threads have hitherto been generally made; and on the past history of metallic threads and sutures in surgery.

*Modern and Ancient Suture-threads; their Materials.*

Among modern surgeons silk is the material most generally employed for forming the threads which they use, both to stitch together the lips of wounds, and as ligatures for the deligation of the mouths of the blood-vessels cut across by the course of the knife. Some surgeons, however, prefer for these two purposes threads made of flax or hemp. Various other materials from the animal and vegetable kingdoms have been at various times suggested and tried as surgical threads and ligatures, such as silk-worm-gut; cat-gut; wool; inkle, hairs; strips of leather, of parchment, and of buck-skin; strings of tendon and of nerves; lines of isinglass; caoutchouc; cotton, etc.

In olden surgery threads of flax, hemp, and latterly of silk, seem to have been most commonly employed for sutures (a). Some forms, however, of surgical threads that are supposed to have been first proposed in modern times were not unknown in ancient times. For instance, there has been some discussion as to who first proposed surgical threads made of animal materials. Catgut was publicly suggested as a proper substance for sutures and ligatures in 1813 by the learned Dr. Thomas Young (b); and it has been doubted and questioned

(a) Few or none of the ancient medical authors speak explicitly as to the material of which their surgical threads were composed. In one passage Galen incidentally alludes to suture threads being made of lint or wool. (Kuhn's Galen, vol. xviii. B. p. 752; or De Med. Off. II. 10.) Paulus Ægineta mentions threads of wool for stitching wounds of the abdomen. (Dr. Adams' Translation, vol. ii. p. 260.) Fabricius Hildanus recommends the vessels in amputation to be tied, when deligation is used, with a hempen thread, "filo cannabino;" and he further speaks of sewing the edges of the wound together with silk, "filo equali ac levi quale est sericum." (Opera, pp. 814, 815.) Severinus advises his followers to use for wounds a slender suture thread of cleaned cotton, "funiculum tenuem e gossypio mundo." (De Efficaci Chirurgia, cap. cxlii.) Fallopius in his treatise on wounds makes the following observations on the best threads for suture:—"Filum autem sit robustum, sed non nimis crassum nec durum. Tertio sit æquale, ita ut præter æqualitatem non habeat nodos interpositos, nec sit putrescibile, quare fila ex gossypio, vel lana non sunt opportuna. Galenus autem (lib. 3, Meth. Cap. ult.) affectebat filum molle ac atissimum, unde disciebat ipse filum Cætanum optimum esse; vel loco ejus utebatur sericino; quare filum lineum sit vel sericinum lineum autem Brixieus optimum esse, et nunquam marcescit, ipso ergo utendum est vel sericina materia, quæ itidem optima est. Filum præterea sit album, vel crenesinum tantum, nigrum enim vel alio colore infectum malum est." (Opera, Tom. II. p. 177.)

(b) See Dr. Young's Introduction to Medical Literature, 1813. "I have often (says Dr. Young) wished to try ligatures of catgut which might be absorbed."—p. 448. In the Edinburgh Medical and Surgical Journal for 1818, vol. xv. p. 155, Dr. Young states that he proposed catgut ligatures to several surgical friends "ten years before," or in 1808.

VOL. XXXVII. No. 975. NEW SERIES, No. 414.

whether the proposal to use animal ligatures was or was not made earlier in America by Dr. Physick of Philadelphia (c). But in all probability catgut, the form of animal thread or ligature that has been most frequently tried in modern practice, was employed in surgical sutures eight or nine hundred years ago. The celebrated Arabic writer Rhazes, who practised at Bagdad about A.D. 900, speaks (d) of stitching up wounds of the abdomen with a thread made of the string of the lute or harp ("corda liutti vel cithare") (e). And another Arabian author, Albucasis, who lived a century or two later, alludes in the same class of wounds to stitching a wounded bowel with a fine thread made of the twisted intestine of an animal, "filo subtili, quod absterum est ex intestino animalis anneo" (f).

*Uses of Metallic Threads in Olden Surgery.*

Metallic threads have been used for various purposes in surgery from the earliest historical periods (g); but not as sutures for wounds, or ligatures for vessels. They have been employed, for example, in surgical practice for the following objects:—

1. In adjusting fractures of the lower jaw, Hippocrates, among other more important directions, advises that, after the broken ends of the bone are placed in apposition, the teeth on either side of the wound should, if they be disturbed and loosened, be tied together, two or more of them, with a gold thread (h). Paulus Ægineta (i), and after him various Arabic authors, recommends a thread of gold to be applied in the same manner for the same injury; and Wallner (k) has in modern times, for the same purpose, bound a silver thread around the front teeth in central fractures of the lower maxilla.

2. In attempting the radical cure of inguinal hernia, some Surgeons of the middle ages, as Bernard Memis (l), Franco (m), Fallopius (n), Ambrose Paré (o), etc., applied what they termed the "golden stitch," the "golden tie," or "*punctum aureum*," to the neck of the hernial sac, surrounding and constricting it, with the exclusion of the spermatic vessels and cord, by a golden thread, after it was cut down upon, and the bowels returned out of it into the abdominal cavity. This golden thread was left permanently *in situ* around the neck of the sac, sometimes with, as described by Fallopius, a slim defensive gold ring or crescent around the cord (*circutum seu semicircutum ex auro non valde crassum*), and the cutaneous textures healed over all. Besides applying a

(c) Reese and Jamieson's American Edition of Cooper's "Surgical Dictionary," article, "Ligature." "To our distinguished countryman, Professor Physick, of the University of Pennsylvania, is undoubtedly due the honour of having first introduced in 1814, what is known as the animal ligature into Surgical practice. His ligatures are made of Chamois leather."

(d) Continens Rasis, lib. xxviii. ; p. 344, of Venice edition of 1509.

(e) At least the strings of the ancient Egyptian, and hence probably of the Arabic harp, were made of catgut. "The strings of Egyptian harps were," says Sir P. Gardner Wilkinson, "of catgut, as of the lyres still used in Nubia." (Popular Account of the Ancient Egyptians, vol. i. pp. 111 and 118, etc.) "Wiro strings (he elsewhere observes) were not used by the Egyptians in any of their (musical) instruments, catgut being alone employed."—Ib. p. 125. The strings or cords of the old Greek harp were, in the time of Homer, formed, as we learn from one of his similes in the Odyssey, of the twisted intestine of the sheep, *ἐκ σπέρματος ὄντος βοῦς*, Book xxi. xl. 408. The word "cord," as applied to the strings of the harp, etc., is itself, in fact, sufficiently indicative of the material of the strings, as originally the term *χορδή* simply signifies Intestine.

(f) Methodus Medendi, lib. II. c. 85.

(g) It is perhaps not undeserving of remark that gold and silver seem to have been drawn into wires, and in this form used for embroidery, etc., from a very early era. Gold wires and their mode of manufacture, are referred to in Exodus (chap. xxxix. 3.) "Silver wire was," according to Sir Gardner Wilkinson, "known in Egypt about 3500 years ago, being found at Thebes of the third Thotmes. It was used nearly as early as gold wire, which we find attached to rings bearing the name of Osirtasen the First, who lived more than 600 years earlier." (Wilkinson's Ancient Egyptians, vol. ii. p. 82.)

(m) Traité des Hernies, pp. 59, 60.

(n) Opera Omnia, tom. ii. p. 313.

(o) English edition of Paré's works, p. 300. Paré's account is accompanied with sketches of three instruments required for performing the "*punctum aureum*." He figures,—1. a crooked needle, like the modern aneurism-needle, "with the golden wire put through the eye" of it; 2. mallets or pincers to remove the superfluous ends of the wire; and 3. mallets or pincers to twist the ends of the wire together. These instruments very precisely resemble some of those proposed to be used in applying metallic sutures in modern times.

permanent gold thread or wire for the cure of hernia, Paré speaks of occasionally using, for the same purpose, a temporary wire or thread of lead.

3. One mode of treatment long pursued in the management of fistula in ano consisted in passing a flaxen thread or ligature through the fistula and bowel, and gradually cutting through the intervening tissues, by the constriction and pressure of the ligature. This operation is described at length in one of the essays usually included among the Hippocratic writings (p). Foubert, a French practitioner of the last century, substituted a metallic or leaden thread for the flax thread formerly employed in this operation (q). The practice of dividing the structures placed between the bowel and the tract of the fistula with a ligature of lead was, with various modifications, subsequently adopted by Bosquet, Desault, Sebatier, and other continental surgeons.

4. From an early period in surgery polypi have been removed by cords or ligatures applied and tightened around their pedicles (r). In the sixteenth century, Gabriel Fallopius recommended a thread or wire of brass, steel, or iron, like that used in harpsichords (*filum aeneum, vel chalybeatum satis crassum, vel ferreum, ex quo arpicorda constituuntur*), introduced through a silver canula, as the best ligature for the purpose of strangling the base of nasal polypi (s); and a century ago, Levret (t) called the attention of the profession to the advantages of removing uterine and other polypi by the constriction of a silver wire, introduced through a double silver canula. Both of these forms of metallic ligature have been adopted by various followers.

#### Use of Metallic Pins for Sutures.

In the preceding instances the metallic wires or threads were not used as suture threads, to unite the edges and walls of wounds in the soft parts. And when first metals were used for this last purpose, they were employed in the form of fixed bodies, and not as flexible threads. For when the ancient Surgeons kept the lips of some of their wounds united for the requisite time by the metallic pins of their surgical fibulae, and when, in later times, the metallic needle of steel, bronze, silver, or gold was left in for a few days for the same purpose, in the well-known form of the twisted suture in hare-lip, etc., the material of the suture was so far essentially metallic.

#### Use of Metallic Threads for Sutures.

The idea itself of employing metallic threads for surgical sutures is not entirely modern, however much the practice may be deemed so. In his learned dissertation on the "Acia" of Celsus, John Rhodius alludes to many different forms of thread, as the *filum*, "*lineum, laneum, sericum, xylum, aureum, argentum, ferreum, plumbeum* (u)." After speaking of the employment of gold and iron threads in the industrial arts, he alludes to the question of these two metallic threads being capable of use in surgical sutures; and evidently without ever having tried them, he condemns them as unfit for such a purpose. "*Alterutrum certè subtile admodum continendis vulnerum oris sine evidenti doloris molestia vix conferre potuit.*"—p. 192.

During last century, however, metallic sutures appear to have been used, in some isolated examples, by one or two Surgeons. Thus, Purmann, "Chief Chirurgion to the

City of Breslau, in Germany," as he is styled on the title page of the English edition of his "*Chirurgia Curiosa*," used, with alleged great advantage, metallic sutures in wounds of the tongue. The metallic sutures which he employed consisted of what has been specially recommended in modern times, viz. silver threads or silver wire (v). Needles of gold and silver were long preferred by most surgeons in applying the twisted suture for the cure of hare-lip. In his "*Elements of Surgery*," published in 1746, Mr. Mißles speaks of employing silver and gold threads in the operation for hare-lip instead of pins, and figures a needle fitted to draw these metallic threads through the sides of the cleft lip (w).

The first Surgeon in our own times who appears to have actually used metallic threads in practice, was the late Professor Dieffenbach of Berlin. In a paper on Staphyloraphy published in 1826, he has detailed several instances of that operation, in which he used leaden thread to unite and keep united the sides of the divided palate. He preferred for this purpose threads of lead to threads of silk, as he found the ends of the leaden thread could be made by mere twisting of their elongated extremities, to bring into contact the raw sides of the wound more easily than could be effected by attempting to tie and knot the ends of silk threads, by introducing the fingers so deeply within the cavity of the mouth (x). "The difficulty," says Professor Fergusson (y), "of keeping the first noose steady has often been alluded to; the lead ligatures, by being twisted together, obviate this difficulty." The metallic suture in staphyloraphy has been alluded to by many later surgical writers (and modified by some), as, for example, by Mr. Liston in 1831 (z), Velpeau (aa), Pancoast (bb), etc.

Metallic sutures have been adopted in other plastic operations besides that of staphyloraphy. Gosset stitched together the sides of a vesico-vaginal fistula with gold wire, the gold threads being left in for twenty-one days (cc). In his "*Practical Essays on Plastic Surgery*," Mr. Spencer Wells observes: "The lead suture is sometimes useful in deep operations. A piece of soft lead wire is armed at both ends with a short needle. These are passed, by means of forceps or a needle-holder, from within outwards, and the needles removed. The ends of the lead wire are twisted together until the wound is brought into apposition. They are then cut off. This is the easiest suture to apply in cases of vesico-vaginal fistula when deep-seated. The only objection to its use is the necessity for protecting surrounding parts from irritation caused by the ends of the wire" (dd).

The use of metallic threads has been extended by some European surgeons to the stitching of common surgical wounds. In the British and Foreign Medical Review for

(v) See his *Surgery*, Part I. chap. 6: referred to by Heister in his *System of Surgery*. London Edition of 1757, p. 92. "Purman affirms (observes Heister) that he made use of silver threads in sutures upon this part of the tongue to great advantage."—p. 92.

(w) *Elements of Surgery*, p. 277.

(x) In the *Lancet* for 1826, vol. xi. p. 405, in a detailed account of Professor Dieffenbach's operation for Staphyloraphy, it is stated that—"The principal difference in Dieffenbach's mode of procedure from those recommended by Graefe, Roux, Souchet, Jousset, and Alcock, consists in the substitution of a finely-drawn lead wire for the ordinary ligatures. It is necessary that the lead should be as pure as possible; the wire needs only be a little larger than a stout pin; and if used when recently drawn, it will be found just as yielding as a waxed thread. The needles having been uncreased or cut off, the extremities of the ligature are then twisted once or twice slightly round and put on one side of the mouth until the other ligatures are introduced. It is then recommended to commence to close the edges of the velum, by twisting with a forceps the ends of the anterior ligature carefully around each other until the edges of the wound are brought into contact. The twisted wires are to be cut off within about a quarter of an inch of the palate, and turned forward upon the roof of the mouth. The second ligature is to be managed in the same manner, and so the third, or as many as there may be. Should the inflammation be so violent as to cause great tumefaction of the parts, the ligatures may be untwisted to the necessary extent to relieve the tension, without altogether setting the edges free, and the wire may be again twisted tighter when the inflammation subsides. To remove these ligatures it is only necessary to cut the wire on either side above the twisted part, when the whole ligature may be easily brought away by a little lateral motion.

(r) Some ancient authors recommend the ligature to be pulled alternately at either extremity, or used with a sawing motion, like that used in working the *ecraseur* of M. Chassaignac in the removal of polypi and other parts. Rhazes indeed advises the ligature thrown around the base of the polypus to have knots placed upon it at short distances that the Surgeon may thus exert with it a greater sawing power. (*Divisio morborum*, cap. xlii. p. f. 62.) Other Arabian authors, as Albucasis and Avicenna describe the same operation of sawing through the stalks of polypi with knotted threads. Mesue recommends for the purpose a ligature made of several horse-hairs tied together with knots. (Adams' *Paulus Aeginata*, vol. ii. p. 291.) In the thirteenth century, the Italian Surgeon, Bruno, the reputed friend of Petrarch, orders these sawing knots to be placed upon the ligatures at about the distance of a finger breadth from each other; and whenever the root of a nasal polypus is very deep he recommends the extremities of the knotted ligature to be pulled alternately till the polypus is detached. (*Chirurgia Magna et Parva*, lib. ii. c. 12.)

April, 1846, p. 286, it is stated that platinum wire as a suture-thread has thus been "successfully employed at Guy's Hospital by Mr. Morgan." One of Mr. Morgan's colleagues at that Hospital, the late Mr. Bransby Cooper, in his "Lectures on Surgery," published in 1851, when speaking of the treatment of common surgical wounds by the interrupted suture, observes that this, "the interrupted suture, is the one most frequently used by Surgeons, and silk is the ligature generally used; but platinum wire is preferred by some Surgeons. As, however, it is rarely necessary or right to leave the sutures longer in the wound than forty-eight hours, I think (Mr. Cooper adds) it signifies little whether platinum wire or silk be employed" (ee). Again, Mr. Guthrie, when describing the treatment of wounds left by amputation, directs that "the common integuments of the stump should be drawn together in primary amputations by sutures formed of flexible leaden wire; by threads of silk, if leaden wire are not obtainable" (ff).

But in America the subject of metallic ligatures has met with more attention than in Europe. In 1832, Dr. J. P. Mettauer, of Virginia, employed them with perfect success in operating in a very aggravated case of laceration of the perineum and rectum, produced, the year previously, by a tedious labour. The laceration extended as high as three inches upwards, along the anterior wall of the rectum. After sufficiently removing and denuding the hardened edges of the lacerated cleft, and the parts exterior to them, Dr. Mettauer stitched carefully together the abraded surfaces with ligatures of lead wire (gg). "As the ligatures were applied they were tightened, so as to bring the abraded surfaces in contact; and then their ends were twisted together, and cut off of convenient length. About twelve ligatures were required to close the wound. From time to time the ligatures were tightened by twisting them, and the vaginal margins of the laceration cauterized with nitrate of silver to favour the formation of granulations, which it was judged would greatly strengthen the union in this part" (p. 114). The bowels were constipated for four days. The leaden suture threads were not removed till six weeks, "the parts having united perfectly." In concluding his account, Dr. Mettauer observes, "leaden ligatures were preferred in the management of the foregoing case, as experience had proven them, not only less irritating and liable to cut out when tightly drawn than any other material with which I am acquainted, but infinitely more convenient and effective in maintaining a uniform and perfect apposition by the ready facility of simply twisting them, and a proof that the leaden ligature may act forcibly for a long time without cutting out. When they were removed in the present instance, it could not be perceived that any material encroachment had been made upon the margins of the cleft" (p. 115).

Four years after recording his first case in the American Journal of Medical Sciences, Dr. Mettauer reported six additional instances in which he had operated for extensive lacerations of the perineum. "In all of those cases," he states, "the recto-vaginal wall was completely divided, so as to convert the two passages bounded by it into one" (hh). Six of the operations were attended with complete success. In the seventh case, the wound partially tore open some weeks subsequently under the distension produced by the passage of "a large indurated mass of feces, causing intense suffering;" and the patient had not yet submitted to a second operation for her cure. In all the cases in which he operated, Dr. Mettauer used the leaden thread as a suture; cutting it out, however, earlier than in his first case, or apparently from eight to twelve days after its insertion; and leaving the extremities of the wire longer than at first, in order that they might be more readily seized and tightened by an additional twist or two, if they offered to become loose during the first few days following the operation.

(gg) A case of ununited Parturient Laceration of the Recto-Vaginal Septum, successfully treated with Metallic Ligatures. By John P. Mettauer, M.D., of Prince Edward county, Virginia; in the American Journal of Medical Sciences for 1833, vol. xiii, p. 113.

(hh) "I will only," Dr. Mettauer again observes, "remark that the lacerations were extensive, none less than two inches and a-half in length."—American Journal of Medical Sciences for April 1847, p. 314.

In concluding this contribution, Dr. Mettauer observes, "My experience leads me to believe that every case of the afflictive accident is completely remediable. I decidedly prefer the metallic suture in the treatment of this infirmity. With it we are enabled to close and confine the denuded margin of the fissure with more ease and certainty than with the silken or thread suture. And should the least gaping of the wound take place, a few twists of the free ends of the wires will enable us to close it up again. The leaden suture, too, does not cut out as soon as silk or thread" (ii).

In the same year (1847) in which he published this second essay, on the cure of lacerated perineum with metallic sutures, Dr. Mettauer published an account of some cases of vesico-vaginal fistula which he had treated on similar principles. In his first case the opening in the back wall of the bladder was "fully the size of a Spanish milled dollar, and nearly circular." Its edges were denuded and brought together with eight leaden sutures; and after the extremities of these sutures were twisted and tightened, the opening was perfectly close in every part of it, and the line of contact of the opposing surfaces measured two inches. A short, light, silver catheter was permanently retained in the bladder. On the third day the wires were tightened, and again on the seventh. On the thirteenth day the ligatures were removed, and perfect union was found to have taken place along the whole line of contact. The cure was complete, and the woman bore two children subsequently without any return of the accident. Dr. Mettauer operated in five other cases of vesico-vaginal fistula, but not always with the same success. In his second case the fistulous opening was diminished, but not obliterated, after eight operations. In two of the six cases Dr. Mettauer employed thread sutures, but he did not "find them to answer so well as the metallic." His results, however, on the whole, were so favourable as to induce him to conclude with the strong allegation, "I am decidedly of opinion that every case of vesico-vaginal fistula can be cured, and my success justifies the statement."

Dr. Marion Sims, formerly of Montgomery, Alabama, now of New York, published in 1852 an essay on "The Treatment of Vesico-Vaginal Fistula" (kk), describing his mode of operating, and his specialities of management in this class of affections. In this essay Dr. Sims, among other suggestions, recommended the lips of the fistula, after they were refreshed by the surgeon's knife, to be held together by threads of silver wire used as a suture. Latterly a "Woman's Hospital" has been established in New York, principally for the treatment of fistulae and other injuries resulting from parturition, and Dr. Sims has, as Surgeon to that institution, had ample means of proving the valuable and happy results of his treatment. His great and acknowledged success in the cure of urino-vaginal fistulae, and their allied lesions, he himself attributes principally and essentially to the employment of sutures of slender silver wire instead of sutures of silk, etc. At the last anniversary meeting of the New York Academy of Medicine Dr. Sims read, and has lately published, a discourse upon the use of "silver sutures" (ll), displaying (to adopt his own words) "all the ardour and enthusiasm of a devotee." In this discourse he proposes to extend—and relates, indeed, various cases, showing that he had in his own practice extended—the use of silver sutures from vesico-vaginal fistulae to all the common wounds and operations of surgery. Speaking of silver wire as a suture, he remarks, "From the day its wonderful effects were witnessed in vesico-vaginal fistulae in 1849, I have never used any other suture in any department of surgery" (p. 32); and "I declare it (he elsewhere observes) as my honest and heartfelt conviction that the use of silver as a suture is the great surgical achievement of the nineteenth century" (p. 8).

Dr. Sims further indulges in the following enthusiastic and prophetic remarks regarding the value of the silver suture and its "universal applicability in general surgery:" "It is (he says) to revolutionize surgical dressings, and to ensure more beautiful and prompt cures. With it, properly

applied, there can be no gaping wounds to heal by the suppurating process, where there is skin enough to cover a stump; and in many cases erysipelatous inflammation, and even hospital gangrene, may be averted by substituting it for silk as a suture. After all amputations we must use sutures of some sort; and how often do we see silk ulcerating out, and creating such tendency to suppurating, that we are compelled to remove them before there is sufficient union to resist the retraction of the tumefied flaps. But with silver there is no inflammation, no suppuration, no cutting out of sutures, no gaping or retraction of flaps, and therefore no necessity for disturbing the dressing till all is firmly united and permanently well. This," Dr. Sims adds, "is no vain imagining; though enthusiastic, I am not wildly so, for all this has been familiar to me for the last eight years, and I but speak what I know. The next eight years will not find an educated physician anywhere who will dare to use silk sutures, for the silver-thread will now become as essential to the dressing case, as the needle itself; and if I may be allowed to venture a prediction, I will say that fifty years hence the statistics of our Hospitals will show a vast improvement in their bills of mortality after great operations, and this improvement will be due mainly to the use of silver as a suture. Look at its results in injuries of the vagina. Before this discovery, operations for vesico-vaginal fistula, and its congenic affections, were often attended with risk to life, while a cure was a mere accident. But how is it now? Why, every case is easily and perfectly curable that has tissue enough to render any operation whatever practicable; while a failure is the exception to the rule. Besides, there is not the least risk to life, as there is never any fever, or the slightest constitutional disturbance. I am not claiming too much for this suture when I say, that the same relative results must be attained in all other surgical operations requiring sutures, if the same method be adopted. My language is nowise extravagant; and I shall yet live to see the day, when the whole Profession of the civilized world will accord to this simple discovery the high position of being the most important contribution as yet made to the surgery of the present century."—*Pp. 44 to 46.*

The very earnest and unusual terms in which Dr. Sims thus describes the advantages of silver sutures, indicates at least a profound and intense conviction on his part of their great and unqualified superiority over sutures of silk and common thread. In the next part we shall endeavour to inquire into the truth and value of this opinion regarding metallic, as compared with organic threads.

### HOSPITAL NOTES.

#### DIFFERENTIAL DIAGNOSIS OF OVARIAN DROPSY AND ASCITES.

No fewer than four cases have recently come under our notice in which patients suffering from ovarian dropsy had been subjected to prolonged diuretic and mercurial medication, in the belief that the disease was hepatic ascites. In one case, a short time ago, in a large metropolitan Hospital, the reverse mistake was made, and the peritoneal cavity injected with iodine, in the hope of obliterating an ovarian cyst, which, as the autopsy a few days afterwards proved, did not exist. Rumour states that one or two other accidents of the same kind have occurred since the iodine-injection plan came into vogue, but we are not in a position to substantiate them. Facts like these prove that the differential diagnosis between these two affections is either not so generally understood as it ought to be, or else that it is a matter of extreme difficulty. Now, there is one sign which hitherto we have never found to fail, but which I, we believe, as compared with its value, but little known. In more than one work on the diseases of women we find no mention of this symptom, although in extreme cases it is the only one which is available. The sign referred to is percussion of the lumbolateral region. If in a case of ascites in which the dis-

tension is so great that the hydrostatic line of level in front is not changed by posture—and it must be remembered that only in ovarian cases in which the cyst is so large as to simulate this extreme condition ought any difficulty to occur—if, in such a case, the patient be made to sit up in bed, and the loins be percussed, it will be found that the note is the same (usually dull) on both sides. If an ovarian case, no matter how great the distension, be treated in the same way, one loin will be found to be clear, and the other quite dull. The explanation is obvious; in ascites the air-containing coils of gut float as far forwards as their mesenteric attachment will permit, while in the case of an ovarian cyst, they are pushed over to the healthy side. It is not easy to conceive any condition of things, excepting entire exclusion of air from the whole tract of intestines, which could diminish the trustworthiness of this symptom. It indicates also, with unflinching accuracy, on which side the ovarian cyst, if it exist, has originated.

#### ADHESION OF CALCULI TO THE BLADDER.

Many Surgeons have expressed doubts as to whether calculi ever became really united to the bladder, and attribute to mistaken impressions during the performance of the operation the statements of lithotomists as to their having encountered difficulties in removing the stone on account of adhesions which it contracted. There can be little doubt but this occurrence is talked of much oftener than it really occurs, but that it does so occasionally is equally beyond reasonable question. Several instances are on record in which calculi were found after death occupying the bladder and united by organic adhesions to its walls, and with such in remembrance it is not fair to set down all those in which the operator's impressions are the only obtainable evidence, as mistakes or as excuses for the indexterous use of the forceps. A case in which the evidence in support of the belief that the stone was really adherent, was unusually strong, has just occurred to Mr. Henry, at the Middlesex Hospital. The patient was a boy aged 11, in whom symptoms of stone had for long existed, but of late with considerable mitigation. A large calculus was easily detected. In the operation, Mr. Henry stated that he found it connected with the anterior part of the bladder, and difficult to reach. Repeatedly it eluded the forceps, and was eventually only seized by the aid of firm pressure made over the lower part of the abdomen. When extracted, its exterior presented some shreds of organized membrane firmly attached. These shreds were submitted to microscopic examination, and were then found to present all the characters of granulation stricture undergoing organization. The lad recovered, and so happily no opportunity was afforded for inspecting the interior of the bladder.

#### SILVER-WIRE SUTURES.

The relative advantages of silver wire over silk and hemp as a suture will no doubt be soon decided. Dr. Marion Sims' advocacy of them, however unmeasured in its terms, will probably induce their extended trial. Mr. Baker Brown speaks most strongly in their favour in the closure of vesico-vaginal fistula, and has had several successful cases. From the result of a case in which we employed them for the closing a large cutaneous incision, we quite believe that they irritate much less than silk, and do not so readily cause ulceration. Should further experience endorse this conclusion, their uses will be very extensive, more especially in the various departments of plastic surgery.

**ADULTERATION OF FOOD.**—Mr. Scholefield has a notice on the order-book of the House of Commons to bring forward a Bill to prevent the adulteration of articles of food and drinks.

**IMMENSE COOKING APPARATUS.**—The Visiting Magistrates of the Middlesex County Lunatic Asylum are about to have constructed a gas cooking apparatus, calculated to cook for fifteen hundred persons daily. Mr. Sharp, of the Southampton Gas Works, has been consulted respecting the plans and construction of this, the largest application of gas to culinary purposes. The baking compartments are to be capable of cooking eighty-four meat pies.

THE PROVINCIAL  
PRACTICE OF MEDICINE AND SURGERY.

STATISTICAL REPORT OF THE PRINCIPAL  
OPERATIONS PERFORMED DURING  
THE YEAR 1857.

(Continued from page 481.)

THE subjoined Report comprises the following Hospitals:—Addenbrooke's (Cambridge), the Bristol General, the Cheltenham General, the Cumberland (Carlisle), the Derby General, the Dorset County (Dorchester), the Dundee Royal Infirmary, the Glasgow Royal, the Gloucester, the Hull, the Leeds, the Leicester General, the Liverpool Royal, the Liverpool Southern and Toxteth, the Queen's, Birmingham, the Sheffield General, the South Staffordshire (Wolverhampton), the Staffordshire General (Stafford), the Sussex County (Brighton), the West Norfolk and Lynn (Lynn), the York County.

EXCISIONS OF BONES AND JOINTS.—*Concluded.*

*Case 22.*—Addenbrooke's: Mr. Humphry.—A girl, aged 18, pale, but in tolerable health, for seven years the subject of diseased knee-joint. The disease had been much aggravated by a sprain received three weeks before admission. There was much swelling, but no abscess had ever formed. Excision of the joint was performed. The patella, as well as the extremities of the two bones, was removed. The synovial membrane was found thickened; the cartilages were extensively ulcerated, and the ends of the bone were united by firm fibrous bands. Profuse suppuration followed the operation, but the wound gradually closed. Six months afterwards several sinuses still remained open. Under treatment. *Case 23.*—Addenbrooke's: Mr. Humphry.—A healthy woman, aged 27, was admitted with chronic disease of the knee-joint, consequent on a kick received nine years before. Excision of the joint was performed on October 25. The patella was removed, and the synovial membrane, which was much thickened, was dissected away; scarcely any suppuration followed, and the healing process was remarkably rapid. She was up within six weeks of the operation, and was discharged at the end of the tenth week, the bones being firmly united. *Case 24.*—The Hull: Mr. Craven, jun.—A strumous lad, aged 9, had suffered from disease of the right knee for two or three years. Excision of the joint was performed, the long semilunar incision being adopted; the patella was not removed. The case progressed well, and at the date of report ankylosis was almost complete. Under treatment. *Case 25.*—The Hull: Mr. Huntingdon.—A healthy man, aged 30, was admitted in consequence of an injury to his elbow-joint, inflicted by a circular saw. The olecranon process and the inner condyle of the humerus were cut through, but the vessels were uninjured. Mr. Huntingdon sawed off the other condyle, and removed also a further portion of the ulna and the articular surface of the radius. The arm was laid in a straight splint for three weeks, and afterwards placed on an angular one. The parts healed well, and a good amount of motion was secured in the new joint. *Case 26.*—The Dundee: Dr. Crockatt.—A strumous man, aged 20, was admitted, with disease of the right elbow-joint, consequent on an injury. The joint was excised in the usual manner, and a good recovery, with a slight motion in the new joint, ensued. The articular surface of the ulna, and the lower end of the humerus, were extensively ulcerated. *Case 27.*—The Brighton: Mr. Lowdell.—A girl, aged 14, the subject of strumous disease of the elbow-joint, of eighteen months' duration. Excision was performed in the usual manner, and a good recovery followed. She left the Hospital three months after the operation, having then a fair amount of motion in the joint, which was daily improving. *Case 28.*—The Glasgow.—A strumous boy, aged 10, the subject of chronic disease of the hip-joint. Excision of the head of the femur. Recovery. *Case 29.*—The Glasgow.—A man, aged 33, in good health. Primary excision of the ankle-joint, in consequence of a compound dislocation. Recovery. *Case 30.*—The Glasgow.—A strumous girl, aged 15, the subject of chronic disease of the elbow-joint. One ankle was also affected. Excision of the

elbow was performed, but the child sank under hectic exhaustion at the end of the second month. *Case 31.*—The Glasgow.—A boy, aged 15, the subject of strumous disease of the elbow-joint. Excision. Recovery. *Case 32.*—The Glasgow.—A boy, aged 11, for nine months the subject of strumous disease of the elbow-joint. Excision. Recovery. *Case 33.*—The Glasgow.—A girl, aged 18, for four years the subject of strumous disease of the knee-joint. She was in much reduced health. Excision of the joint was performed in the usual way on July the 9th. A good recovery followed, and the consolidation of the parts was complete by the middle of December. Her general health had much improved, the ankylosis was perfect, and she could bear weight on the limb; the shortening was about an inch-and-a-half. *Case 34.*—The Glasgow.—A boy, aged 10, for four years the subject of diseased knee-joint. Excision in the usual manner on December 28. At the date of report the case was doing well. *Case 35.*—The Glasgow.—A man, aged 33, was admitted with a compound dislocation of the elbow-joint, caused by a fall from a scaffold. The heads of the radius and ulna were broken, and were excised. The articular surface of the humerus was not interfered with. Recovery, with complete ankylosis, resulted. *Case 36.*—The Glasgow.—A man, aged 27, was admitted on November 3, having had his elbow-joint opened by a circular saw; the olecranon and lower end of humerus had been injured, and were consequently removed. At the date of report the case was doing well. *Case 37.*—The Liverpool Royal: Mr. Bickersteth.—A delicate looking boy, aged 11, the subject of diseased knee-joint. Excision was performed; the semilunar incision being adopted. The joint was found quite disorganized; the cartilages being almost wholly gone. The patella was not removed. A profuse discharge followed, and the boy was for some time in a critical condition. At the date of report there seemed good reason to hope the limb would be saved. *Case 38.*—The West Norfolk: Dr. Cotton.—A thin, spare woman, aged 45, was admitted with the intention of submitting to amputation of the thigh on account of diseased knee-joint. The disease had existed twenty-five years, and there was a large ulcer with fungoid granulations on the inner side of the joint. Excision of the joint was performed in the usual manner on September 28. She recovered well; and at the date of report was able to bear considerable weight on the limb. *Case 39.*—The West Norfolk: Dr. Cotton.—A delicate girl, aged 16, was admitted with chronic enlargement and contraction of the knee-joint: the disease was of nine months' duration. The joint was excised in the usual manner on September 28. For some time she appeared to be doing well, but she subsequently sank into a state of extreme anæmia, and so died in the beginning of the ninth week. Anasarca had been present during the last few weeks. The autopsy showed no disease of either lungs, heart, or kidneys, nor were there any evidences of pyæmia having existed. No osseous union had taken place between the extremities of the bones. *Case 40.*—The West Norfolk: Mr. Kendall.—A girl, aged 3 years, the subject of strumous disease of the knee-joint for more than twelve months. Excision of the joint was performed, and she made an excellent recovery. At the date of report she was able to bear weight on the limb. *Case 41.*—The Queen's Hospital, Birmingham: Mr. Sands Cox.—A healthy boy, aged 3, was admitted on account of a bony growth, occupying the lower part of the scapula: it had been gradually increasing for two years. Mr. Cox excised the whole of the bone beneath its spine, by means of a chain saw passed under it. No vessels required ligature, the hæmorrhage being arrested by pressure. The tumour proved to be a flat-based exostosis. The healing was retarded by an attack of erysipelas. He was discharged well six weeks after the operation. *Case 42.*—The Leeds: Mr. Teale.—A boy, aged 9, the subject of diseased tarsus. The os calcis, and the greater part of the astragalus were excised. The suppuration was profuse for some weeks, but at length the parts healed well. At the time of discharge from the Hospital, only a very small sinus remained. *Case 43.*—The Glasgow.—A boy, aged 8. Excision of the os calcis on account of strumous disease. Recovery.

OPERATIONS FOR CARIES OF BONE (NOT  
EXCISIONS).

*Case 1.*—The Leeds: Mr. Teale.—A sallow unhealthy looking man, aged 30, the subject of carious disease of the head of the tibia. The discharge escaped from a small orifice.

The cavity in the head of the bone was trephined and gouged out. He improved greatly in health after the operation, and the wound slowly healed. *Case 2.*—The Queen's, Birmingham: Mr. Sands Cox.—A boy, aged 11, the subject of carious ulceration of the lower end of the tibia. The gouge was applied, and some small pieces of bone removed. Recovery. *Case 3.*—The Queen's, Birmingham: Mr. Knowles.—A lad, aged 9, who had been for some time under care for carious disease of the tarsus. The sinuses were laid open, and the gouge applied to the diseased surfaces. Recovery. *Case 4.*—The Bradford: Mr. Meade.—A woman, aged 33, the os calcis was gouged on account of caries. Under treatment. *Case 5.*—The North Staffordshire: Mr. Turner.—A man, aged 27, in fair health, the subject of diseased tarsus. The three cuneiform bones were almost wholly removed by gouging. Under treatment.

#### AMUSSAT'S OPERATION FOR ARTIFICIAL ANUS.

A man, aged 49, was admitted on Nov. 4, into Addenbrooke's Hospital, under Mr. Humphry, suffering from obstruction of the bowels, caused by a tumour pressing on the upper part of the rectum. The bowel itself appeared to be quite healthy. His sufferings had been great, and his health much impaired. He stated that he had enjoyed good health until a year before, when for the first time he began to experience difficulty in defecation; eight months ago he had had a stoppage, which had lasted a week. For seven weeks before admission, the bowels had scarcely been relieved at all, only very small quantity of feces having been got away by the frequent use of injections. Under these circumstances it was determined to open the colon in the left loin (Amussat's method). The operation was done with much ease, the bowel being distended by flatus and feculent matter. It afforded the greatest relief, and no unfavourable symptoms whatever followed. At the date of report (December 31), the feces passed freely both by the rectum and by the artificial opening.

#### AMPUTATION OF THE PENIS.

*Case 1.*—The Leeds: Mr. Teale.—A healthy man, aged 77, the subject of epithelial cancer. He stated that the disease had commenced so long ago as twenty years back. The glands in the groin were not affected, but the urethra had become obstructed, and he made water with the greatest difficulty. The whole organ was amputated, and the mucous membrane of the urethra stitched to the skin. When the parts were healed the urethral meatus was freely open. *Case 2.*—The Liverpool Royal: Mr. Stubbs.—A healthy looking man, aged 35, the subject of epithelial cancer of the penis. Amputation. Recovery.

#### OPERATIONS FOR URETHRAL STRICTURE.

*Case 1.*—The Glasgow.—A man, aged 48, for eleven years the subject of stricture. Patient and repeated attempts by dilatation had failed to cure it, and perineal section in the usual method was performed. Recovery. *Case 2.*—The Leeds: Mr. Teale.—A man, aged 43, had been the subject of a very troublesome stricture for several years. No instrument could be passed. Perineal section without a guide was performed. Considerable difficulty was experienced in finding the vesical part of the urethra. The cure was subsequently much delayed by the extreme irritability of the parts, which rendered the use of instruments difficult. Recovery. *Case 3.*—The West Norfolk: Dr. Cotton.—A soldier, aged 40, in tolerable health, but for twelve years the subject of stricture, was admitted on September 29, on account of extensive extravasation of urine into the perineum, and beneath the abdominal fascia. Free incisions were practised, and considerable quantities of pus and decomposed urine escaped. The patient was freely supported by diet and stimulants, and did well. No instrument could be passed through the stricture, and on October 8, perineal section (without a guide) was performed. About an inch and a half of the urethra having been divided, a No. 12 catheter was introduced and retained. At the end of a month the wound had perfectly healed, and no fistula remained. Two months later he called at the Hospital, and stated that he continued quite well: the urethra freely admitted a No. 12. *Case 4.*—The Liverpool: Mr. Bickersteth.—A waiter, aged 27, of sallow complexion, the subject of stricture for several years. The stricture had become much worse during the six months previous to admission. He had had instruments passed at various times, and had once suffered from extra-

sation of urine. On admission, he was treated with warm baths and opium suppositories, and after a few days a No. 5 bougie was passed. He subsequently had a smart attack of catarrh of the bladder; but this yielded to treatment, and his general health improved. Perineal section (on a grooved staff) was performed on March 17. A No. 8 catheter was retained in the bladder for forty-eight hours afterwards. A few days after the operation an attack of jaundice, with bilious vomiting, occurred. At this time the urine passed freely; but in the following week he complained of severe pain about the bladder, and became unable to pass his water. Catheters were now passed, but no urine could be obtained. In the belief that the bladder was distended by blood-clot, the patient was put under chloroform, a grooved staff introduced, and the opening in the urethra enlarged. The finger now could be passed into the bladder without difficulty, but still no urine came. A large gum-elastic catheter was passed by the wound, with no better success. At length, however, on gentle pressure being made on the distended bladder, a large mass of blood-clot was ejected, and about three pints of urine followed. Arterial blood was now observed to be flowing freely from the deepest part of the wound. With some difficulty the vessel was secured on a tenaculum, and a lithotomy tube was afterwards retained in the bladder. The patient afterwards sunk into a feeble state, and death took place on the second day. At the autopsy the liver and both kidneys were found diseased. *Case 5.*—The Bradford: Mr. Parkinson.—A man, aged 28, the subject of an old stricture, the result of injury to the perineum. Not even the smallest instrument could be passed. Perineal section (without a guide) was performed. Death, from urinary infiltration and diffuse inflammation of the cellular tissue followed on the tenth day.

#### OPERATIONS BY THE ÉCRASEUR.

From the reports sent to us it appears that the *écraseur* has been used in a variety of cases in Provincial Hospital practice during the past year. In one case, a man, aged 48, was admitted, under the care of Mr. Kendall, into the West Norfolk Hospital, on account of a large growth of cancer on the left side of the tongue. The growth had existed eight months, but had latterly so much increased as to prevent closure of the mouth, and to impede mastication. At the urgent request of the patient, the whole of the left side of the organ with the diseased mass was removed by the *écraseur*. Profuse hæmorrhage from one vessel followed its separation, but was arrested by a ligature. The operation was performed on July 4th, and on October 18th, the man again came under care with a return of the disease in the base of the tongue and in the glands of the neck. In two cases under the care of the same gentleman, large cutaneous outgrowths from the clitoris and nymphæ occurring in young women, were successfully removed by this instrument without hæmorrhage. In each instance the wound healed well. In the case of a girl aged 20, in the Hull Infirmary, under the care of Mr. Craven, the *écraseur* was employed for the removal of two separate tumours, each about the size of a hen's egg, growing on the side of the face; one of the wounds healed well, the other not so readily. In the site of the latter the disease returned about two months afterwards. In this it had originally been of very suspicious aspect.

#### EXCISION OF TUMOUR FROM FALL.

Dorset County: Mr. Tapp.—Elizabeth Chal, aged 26, re-admitted October, 1857. Has never enjoyed good health. Had small-pox when four years old, and inflammation of eyes, which have never been well since; she has some opacities on cornea, and has lost her eyelashes. States that two and a half years ago she noticed a tumour the size of a pea, situated near the articulation of the left malar with superior maxilla. It grew very slowly for two years, when it began to increase, and when admitted, three months ago, was the size of a walnut, and divided into two parts. Under the constant application of collodion it decreased to one-half its original size, and she left the Hospital September 3, 1857, much improved in every respect. The tumour remained quiet until three weeks before admission, when it began to grow, and has grown rapidly; the two parts into which it was formerly divided have coalesced, and it is larger than it was on her first admission, the skin looking angry and ready to

break. It was removed October 30, the day after admission, and the tumour upon examination was considered to be cancer. She left the Hospital, quite recovered, December 3, 1857.

#### LITHECTASY.

Mary Ann Selway, aged 6 years, admitted October, 1857. Eighteen months ago began to suffer pain in passing water, and at other times as well; viz. when she ran about. About three months before admission, she passed blood with her urine; and for five or six months before admission, the urine passed involuntarily. A sound was introduced, and stone detected, which was removed on the 10th of November, 1858, by dilatation. The patient was able to hold her water during the day, thirty-six hours after the operation, and for three nights before her discharge, November 30, there was no incontinence of urine. Size of stone,—large circumference, 3 inches; small circumference, 2½ inches.

#### AMPUTATION OF THIGH.

Edward Brown, a carter, was admitted December 28, 1857, with a curved wound situate on the inner side of the right thigh, about three inches above the condyle; the length of wound was about three inches, it was caused by being trodden on by his horses while endeavouring to stop them, they having run away. The wound did not appear deep, the edges were clean like an incised wound; it was brought together with sutures, went on well for a day or two, but on removing the sutures, no adhesion had taken place; it took an inflammation and suppurated, the man being feverish and having an unsatisfactory look. On Saturday night, January 9, 1858, at 11 o'clock, hæmorrhage of artificial character occurred to a considerable extent; the wound was immediately enlarged, clots removed, and the vessel sought for, but could not be found. The wound was then plugged with lint, and strictly watched; all went on well until Thursday, January 14, when hæmorrhage recurred, wound again enlarged, clots removed, but no vessel could be found. It was then determined to tie the femoral under the sartorius; but on further examination, the femur in the popliteal space was so much denuded of periosteum, that it was deemed advisable to amputate at the junction of middle and lower third. On examination of the limb, it was found that a small branch, apparently one of the articular, had sloughed at its junction with the main trunk, leaving a small hole in the popliteal. Discharged cured April 1, 1858.

#### REMOVAL OF STONE.

Thomas Hawkins, admitted February 11, 1858, reported to be suffering from symptoms of stone. On admission an attempt was made to pass a sound, but it could not be done, owing to spasmodic stricture; the next day, and a day or two after that, attempts were made, but without success; the sound passing some way down the urethra, but causing great pain, and the water flowing when the attempts were persevered with. Under these circumstances, and as the urine deposited a large quantity of tenacious mucus similar to that obtained in catarrh of bladder, it was resolved to treat him on that principle, by warm hip-baths, etc.; this somewhat improved his condition; and one day when trying again to pass a catheter, the instrument came down upon a hard body, evidently a stone in the urethra, one end of which was situated about one inch below the lower border of the scrotum. The man called my attention to a hard body, which he now told me he had found come down and go back again since September. He further informed me that since September, when he sat, this body came down, but went back when he stood up; he could not ride astride his horse in consequence of this body. On introducing the finger into the rectum, the stone could be felt in the urethra, and evidently of some size; an incision was made in the middle line of the urethra, over the tumour, and a stone extracted weighing 2½ drachms. The man's condition improved, and it was supposed we had got to the bottom of his troubles, but Mr. Tapp thought there might be another, perhaps, and a catheter was again passed some two or three days after, and another stone detected much in the same place, weighing 3½ drachms, and which was removed by slightly enlarging the first wound. The man recovered and was discharged quite well, April 8, 1858.

## Medical Times & Gazette.

SATURDAY, JUNE 5.

#### ON SOME RECENT CHANGES IN MEDICAL EDUCATION AND EXAMINATION.

THERE is no one who wishes well to the Medical Profession who will not view with interest and satisfaction every attempt made to improve the education of Medical students, or to devise more and more efficient means of testing, by examination, the competency of candidates for degrees and diplomas.

It has long been a difficult problem to determine how knowledge can be best infused into the mind on the one hand, and how its acquisition may be tested on the other. On the question of education, some would stimulate the ambition of youth by the alluring temptation of prizes and scholarships for the most deserving students, while others would denounce the prize system as calculated to make only book-worms, and not men of practical acquirements. Some would argue that the various sciences on which the superstructure of medicine is raised should be communicated by means of numerous courses of lectures, while others would maintain that students may learn as much, if not more, in the retirement of their own rooms, and with the aid of appropriate books, than from the discourses of their Professors. As to the subject of examinations, again, while all are agreed as to their importance and efficacy, the utmost diversity exists, both in theory and practice, as to the mode of carrying them out;—some would select examiners from the Medical Teachers of the Universities and Schools, while others would exclude teachers altogether from such duties, on the ground that the examiners might be biased in their judgment by predilections for their own pupils. In all these views and reasonings there is much truth on both sides; but in the absence of any State regulations for the education and examination of Medical students, we are compelled to take matters as we find them; and while we commend the zeal of those bodies in our Profession which endeavour to advance with the progress of the times, we may take the liberty to reprove those which linger in the rear of improvement, and are urged on to exertion only by the force of circumstances.

Some weeks since we alluded to a change about to be effected in the present curriculum of education of students preparing themselves for the diploma of the Royal College of Surgeons; and we are now able to announce that the change which has been some time contemplated will forthwith be carried into operation. The results of this change will be, that while the mere attendance on lectures is diminished, the examinations at the College will be more stringent than heretofore, and will be held upon two separate occasions, instead of one, as at present. The candidate may present himself for his first examination, which will consist chiefly of Anatomy and Physiology, at the termination of the second winter session of his attendance on Lectures and Hospital practice: the second examination will take place at the termination of

the curriculum, and will comprise Surgery and Pathology. It is also understood that a portion of the examination will be conducted by means of written papers; a very excellent plan for eliciting the information of candidates, and a much more satisfactory one than that of mere oral conversation, in which ignorance may sometimes be successfully masked, and ability may remain undiscovered.

It is obvious that by the changes now proposed the system of *grinding* will receive a heavy blow; for when students are compelled to present themselves at two separate examinations held at distinct intervals, and when they are required to *write* their answers, it is quite evident that the plan of cramming a man for examination in a few weeks must soon come to an end; while the diligent student will have the gratification of exhibiting, at progressive intervals, the advance which he has made in the different branches of his Profession.

The compulsory attendance on Lectures is very much diminished in the forthcoming Regulations; for although the subjects of the lectures remain unaltered, a much smaller number of courses is required than before. This will be, no doubt, a great boon to the student, who will thus be relieved from the necessity of attending year after year courses of lectures upon the same subject; while he will have more time to devote to the practical operations of the dissecting-room, and to attendance in the wards of the Hospital. It appears to ourselves that the oral Lectures in the Medical Schools have been too much amplified of late years, and that, in the zeal of each Lecturer to expound in all their details the facts and bearings of his own speciality, the students have been bewildered with an infinity of words; while the great landmarks of the Profession have been almost lost amidst the *verbiage* with which they were surrounded. Not many years since, two courses of Anatomy and Physiology were delivered at each of the Medical Schools in each winter session; and we are not sure that in the present day, when those courses have been indefinitely amplified, our rising Physicians and Surgeons have derived much benefit from the change. It is, of course, desirable that Medical science should be cultivated to its fullest extent, and in all its departments and dependencies; but life is short, and art is long, and the average period allowed to Medical students to complete their curriculum is far too brief to allow them to do more, under ordinary circumstances, than to acquire a fair general knowledge of the theoretical and practical subjects presented to their notice; more especially when it is remembered that a great majority of our alumni are compelled to enter upon the responsibilities of practice at the age of twenty-one.

These considerations, in our opinion, derive still greater weight from the circumstance that the curriculum of the College of Surgeons is extended over only four years—a period, in our judgment, which is barely sufficient to make a man of ordinary capacity acquainted with the outlines of his Profession; more especially when we recollect that out of these four years, the lectures and Hospital practice occupy scarcely two years and a-half, and the rest of the time is pretty well left to the student's own disposal. But perhaps it is necessary to manufacture Surgeons in a short time and at a cheap rate; and in the present demand for Medical men, particularly in the public service, there may be some justification for the plan adopted.

We have received from the Society of Apothecaries of London the Regulations for the new curriculum of education proposed by the Court of Examiners of that body, together with some prefatory remarks by which the Regulations are accompanied. By this document it would appear that the Court of Examiners have altered their curriculum, in conjunction with the Council of the College of Surgeons, and in conformity with the views advanced by the latter body. The number of subjects required by the Apothecaries' Society is

greater than that required by the College, with the exception, of course, of Surgery; but the general features of the two plans are pretty much the same.

In the department of Practical Medicine we perceive that a very important change has been made in the Regulations of the Apothecaries' Society;—for the instruction in Clinical Medicine is now to consist of a distinct course of Lectures on that subject, while the second course of Theoretical Lectures on the Practice of Medicine is abolished, or at least is not made imperative.

It may be interesting to our readers, and especially to the younger part of them, to know that these Regulations will come into effect on and after the 1st of August next; after which period the examinations will be divided into two parts, to be held on two separate days. At the College of Surgeons, as we have before mentioned, the first examination will comprise, chiefly, Anatomy and Physiology; and the second will embrace Pathology and Surgery. At Apothecaries' Hall, the first examination will include Latin, Chemistry, Materia Medica, Botany, Physiology, and Anatomy; and the second will be chiefly devoted to the Practice of Medicine and Midwifery, together with Pathology and Medical Jurisprudence, including Toxicology.

We alluded last week to the very striking and important novelties introduced into the examination of candidates for the Medical degree at St. Andrew's; and we have only to repeat the expression of our gratification that the Medical Professors of that University have shown themselves so sensible of the necessity of progress in Medical education.

#### THE WEEK.

THE prospects of Medical Reform will be considerably brightened since the debate which took place on Tuesday night upon the subject. It will be perceived that Mr. Walpole has promised to introduce some amendments into the bill of Mr. Cowper, which may have the effect of reconciling the conflicting views now entertained on this much vexed question. The speech of Mr. Walpole deserves great attention for the ability which it displays, and the lucid views at which he has arrived from a long and careful consideration of the Medical Reform question.

With great regret we learn that the Poor-law Board have completed the series of persecutions to which Mr. Symes of Bridgewater has been exposed by dismissing that gentleman from his office. This cruel proceeding has excited the deepest sympathy for Mr. Symes both in and out of the Profession, and especially in his own town, where the expression of commiseration is almost unanimous. The exception, we regret to learn, is to be found among one or two Medical men, and it is thought with some reason that Mr. Symes has been made the victim of personal animosity. We hope that the matter will not be allowed to rest, and that it will be brought before the notice of Parliament.

We publish this day two documents on the subject of the Royal Medical Benevolent College: one by Mr. Propert, the excellent founder and indefatigable friend of the institution; the other, which is a statement of grievances, by the dissentient Governors, who have called in question the whole policy, past and present, of the Council. As both sides have thus had the privilege of laying their views before the Profession, we hope that at the meeting to be held next week, the subjects in dispute will be discussed with mutual patience and forbearance, and that the result may be an amicable understanding between the contending parties. The Royal Medical Benevolent College is too important an institution to be

undangered in its present career of prosperity by internal discord; and it is most especially to be regretted that the differences which now prevail have originated from the conflicting opinions of those, who, however divided on other points, are all staunch friends of Mr. Probert's patriotic work, and ardent admirers of the enthusiastic energy by which alone such an Institution could have been originated, and brought so far on towards a secure and permanent success.

In another part of the Journal will be found a series of Resolutions lately passed at the Medical Institution of Liverpool, on the subject of the appointments to Medical Charities. It is justly considered that the present method of canvassing the Governors of these institutions by the Profession is undignified and degrading, and is no less annoying to the persons canvassed than to the canvassers. It will be seen that the efforts of the Medical men in Liverpool have been attended with some degree of success, and their recommendations have been acted upon by the Southern Hospital and by the St. Anne's Dispensary, and it is hoped that the principle will be still further extended, not only in Liverpool, but throughout the country.

Among curiosities in Medical literature, the following deserves a place. A French Surgeon visits London in 1856 to examine the contents of its museums in relation to the subject of stricture of the urethra, at the instance, he states, of M. Malgaigne. Having made his examination he hastens to report respecting it to the Société de Chirurgie of Paris. He has discovered, however, that our countryman, Mr. Henry Thompson, of University College Hospital, has made a similar but much more extended investigation some years previously, the results of which formed a portion of the work for which he received the Jacksonian prize of 1852. Accordingly Dr. José Prò adopts the portion of that work (about 30 pages) which relates to the pathological anatomy of stricture, and which Mr. Thompson presents as a *résumé* of the facts which the museums exhibit; simply translates it, and, omitting all mention of Mr. Thompson's authorship, serves it up to the Academy as his own. It met with great favour, and is published in Paris under the name and as the production of Dr. José Prò. Our readers will find a brief analysis and review of it at another page. We understand that Mr. Thompson is taking the necessary steps to claim his rights as an author and as an observer, and we have no doubt he will obtain a full recognition of them by the Société in question.

We beg to direct the notice of our readers to the full Report of the discussion held at Bedford on the 21st ult., on the subject of Consultations with Homœopathic Quacks, which we publish in another part of the present number of our Journal. Amidst the apathy and discord which too often prevail among the members of our Profession, it is quite refreshing to find a large number of our brethren meeting together, and expressing in bold, but most temperate language, their abhorrence of quackery, and their determination to uphold the legitimate interests of our honourable calling. In expressing our high admiration of the conduct of Dr. Paley and Mr. Philbrick, we feel that we only re-echo the sentiments of the whole Profession throughout the length and breadth of the land; and we hope that, although these gentlemen may have suffered some pecuniary loss, and experienced some other annoyances from the late notorious case at Stamford, they will find in the approval of their own consciences and the warm thanks of every well-wisher to Medical science, a reward which will much more than compensate them for any injury they may have received. The Bedford meeting will

certainly not be without its fruits; and we cannot too highly approve of such assemblies for the discussion of points touching our common honour and reputation. One or two men, standing unsupported, might fear to sacrifice themselves in any cause, however good; but a multitude, meeting together, speaks trumpet-tongued to the world; and the warning voice thus sent forth will confirm the steadfast in their honest career, and convey a hint to the waverers which is not to be misunderstood. We would call especial attention to the admirable speech of Dr. Herbert Barker on the late occasion.

We perceive, by a notice which has been forwarded to us by the Society of Arts, that the Council of that Society have appointed a Committee to investigate the subject of mechanical contrivances applied to Medicine and Surgery, to promote improvement in the production of such instruments, to examine and report on the merit of the apparatus submitted to notice, and to recommend rewards for successful invention. The Committee consists of a large number of Medical gentlemen, distinguished in all branches of the Profession; the object of appointing so large a body being to afford material for the formation of special sub-committees, each to consist of at least three or four gentlemen. The Committee unanimously elected Mr. James Luke, chairman, and Dr. Watson, Dr. Budd, Mr. H. C. Johnson, and Mr. Partridge, deputy-chairmen, and Mr. F. S. Haden, and Mr. Mitchell Henry, reporters. It was in contemplation to form Sub-committees on general Medicine and Surgery, and on Dental, Obstetric, Ophthalmic, and Orthopædic Surgery, and also on Philosophical Apparatus applied to the investigation and treatment of disease, and on Veterinary Surgery. At the inauguration of the Committee it was observed by Mr. Wentworth Dilke, in opening the proceedings, that the price of Surgical instruments in this country was much greater than in France, and that although English instruments were superior in temper and quality, it was not certain that this advantage was commensurate with the great difference in price. The present Committee on Surgical instruments is an offshoot of the Great Exhibition of 1851.

Mr. Griffin has just published, in the form of a printed circular, the Report of the late Deputation of Poor-law Medical Officers to the President of the Poor-law Board. This Report has been forwarded by Mr. Griffin to all the Poor-law Medical officers whose addresses are known; but as many changes have necessarily arisen since last January, when the list of Medical officers was made out, we understand that a copy will be forwarded to any gentleman who will communicate with Mr. Griffin to that effect. The document to which we refer is of very great interest, and the result of the deputation to Mr. Estcourt is very fully and accurately reported. We are also happy to perceive that a ray of hope seems gleaming in the distance in favour of that much ill-used class,—the Poor-law Surgeons; for Mr. Estcourt, whether moved by the number and respectability of the gentlemen forming the deputation, or whether convinced in his own mind of the injustice inflicted by the present system, promises to prepare a Bill, during the present session, for the amendment of existing evils. As this promise has been made by Mr. Estcourt, we have no doubt, from the high respectability and integrity of his character, that he will fulfil it; and we may anticipate, before the end of the session, the appearance of a measure which can be maturely considered during the recess. It is most gratifying to record this success, although hitherto partial, achieved by Mr. Griffin's exertions; and we hope that his brethren of the Poor-law Medical service will still rally round and support him, until an adequate measure of Reform is obtained.

The Biennial Festival of the Medical Benevolent Fund will be celebrated by a public dinner, at St. James's-hall, Regent-street, on Thursday next, June 10, under the presidency of the Earl of Granville, and we hope that the attendance of a numerous assembly of our Professional brethren and their friends will bear testimony to the excellence and usefulness of this simple and unobtrusive Medical charity. The chief novelty of the forthcoming celebration (after the dining-room itself, which is one of the great ornaments of the metropolis) will be the presence of the ladies, who may obtain tickets at a very moderate rate, and we trust that gentlemen who attend will induce ladies of their acquaintance to enhance, and partake in, the enjoyment of the festive occasion. Although we have on many previous occasions alluded to the services rendered to many necessitous members of our Profession and their families by the Medical Benevolent Fund, we may take occasion to remind our readers that the objects of this Fund are to relieve cases of urgent necessity, by pecuniary grants commensurate with the resources in hand, and proportioned to the urgency of each case. The relief thus afforded is dispensed by a Committee of gentlemen, meeting periodically at the house of Mr. Churchill, who kindly lends a room for the purpose, thus materially lessening the working expenses; and the recipients of the benefits are not exposed to the trouble and expense of a prolonged canvass, their own misfortunes and the recommendation of some respectable friends being the only solicitation required. The quiet nature of the proceedings, and the private manner in which the relief is administered, in some measure keep the Medical Benevolent Fund out of general view; but those real promoters of charity, who would do with their right hand the good deeds of which their left is unconscious, and who would desire to obviate the exposure of the distress, perhaps temporary and transient, into which some member of our Profession, or his widow or children, may have fallen, will perhaps entertain as high an estimate of this Fund as of some others of which the operations are more public and conspicuous. We leave the consideration of this matter to the benevolent, and we doubt not that a warm response will acknowledge the force and justice of our appeal.

A Bill is now before Parliament, entitled "Friendly Societies Act Amendment," which contains the following:—"And if the said child have been attended immediately before its death by the Medical officer of any Union, on account of such Union, he shall deliver to the parents or friends of the deceased child, upon their application, a certificate stating the probable cause of death of such child, without fee or payment of any kind. Coroners are required to do likewise." No fee is to be paid for such certificate; and thus we see another instance in which the services of Medical men are to be pressed gratuitously into the sphere of public duties.

## CONSULTATIONS WITH HOMŒOPATHIC QUACKS.

### MEETING OF THE PROFESSION AT BEDFORD.

At a large meeting of Medical men held at Bedford, on Friday, May 21st,

Dr. WEBSTER said:—Mr. President and gentlemen, I rise for the purpose of bringing under your consideration a circumstance that has recently occurred in the district of our South Midland Branch of the Association, which has created much excitement, and occasioned much discussion both within and without the Profession. Involving as this matter does many medico-ethical considerations, and happening in the practice of two of our members, a full investigation into

the circumstances, and a decided opinion upon them, may justly be expected of this meeting. I am informed, Sir, that a faithful account has not yet been given to the public; and before entering upon the subject it may be desirable that you, Sir, should request of those two gentlemen, whom we gladly see present to-day, to favour us with authentic details. But before doing so, I would express a hope that our observations and expressions may be of the most temperate character, and that we shall not be led away into any disquisition upon the merits of Homœopathy, it being quite sufficient at the present meeting of Professionally educated gentlemen, to refer to the fact that the so-called system has been weighed in the balance of talent, science, and truthful investigation, and has been ever found wanting. Will you then, Sir, solicit from Dr. Paley, of Peterborough, and from Mr. Philbrick, of Stamford, the account of this case.

Dr. PALEY said, he should have pleasure in stating the facts of the case, which he believed was a very important one. It was that of a gentleman living near Stamford, who was suffering from paralysis of the left side, and had previously suffered from similar symptoms in a much lighter form. He (Dr. Paley) had no doubt that there was some structural disease of the brain, probably of long standing, and he therefore did not think it right to adopt active treatment; retention of urine did not occur till some days after, and then not from any disease of those organs, but as a consequence of the paralysis. Under the treatment prescribed, the patient appeared to him (Dr. Paley) to be doing well; but the wife of the patient, not being satisfied, had been very anxious from the first, that Dr. Bell, a homœopath, should be called in in consultation. Both Mr. Philbrick and himself positively declined to meet Dr. Bell if he came down, and in consequence of this refusal a telegraphic message was sent to Dr. Bell to put off his journey for some time. On Sunday afternoon Dr. Bell came down; and here, in speaking of the conduct of others, he (Dr. Paley) would prefer to use only documentary evidence. In a letter to Mr. Philbrick, the lady says, "In answer to your letter and bill, I beg to say that I requested you and Dr. Paley to meet Dr. Bell on Sunday, Feb. 21, which you both declined to do." In another part she says, "As soon as Dr. Bell saw the patient he was much shocked, pronounced him in imminent danger, desired me to send for his brother, as his opinion was that he would sink in a few days under rhubarb, gentian, etc." He (Dr. Paley) had arranged to go again on Monday; but after Dr. Bell had seen him, a polite note was sent, explaining the circumstances, and declining his further attendance. From an accident this note did not arrive in time, and he (Dr. Paley) and Mr. Philbrick saw the patient together on the Monday morning after Dr. Bell had left. The patient then required the use of the catheter; and before considering what further course they should adopt under the circumstances, they determined first to relieve their patient. This was done, and then Mr. Philbrick was requested to attend with Dr. Bell to perform the necessary operations. After consulting together as to what was the proper course for him (Mr. Philbrick) to pursue, he respectfully but firmly declined to have anything further to do with the case so long as Dr. Bell had charge of the patient. There had been much misrepresentation; but what he had stated were the simple facts of the case. Mr. Philbrick had been accused of "leaving the patient to die," rather than meet Dr. Bell; of having acted from temper, etc. He (Dr. Paley) was present when Mr. Philbrick declined, and he must say that he thought Mr. Philbrick had acted throughout the whole of this painful case with humanity and firmness. The patient was not left in an emergency, the catheter having been used before he left the house. More honourable conduct than that of his friend Mr. Philbrick, he had never met with from any practitioner; and he thought he had been most harshly treated. After Mr. Philbrick declined, he received another letter from the lady, in which she says:—"He (Dr. Paley) will be glad to hear that Mr. Jackson came without making the least difficulty, to perform the operation for the patient this morning; and he has not the slightest objection to meeting Dr. Bell, or acting under his directions, which of course makes Mr. — quite comfortable." In consequence of this intimation, he communicated with Mr. Jackson, who in his answer stated that he was in attendance upon the patient for the purpose of introducing the catheter. In the postscript he stated:—"I have never yet seen Dr. Bell, but he and Mr. Fergusson are coming

down from London to-night, when I shall have an interview with those gentlemen." In his last letter to the lady he (Dr. Paley) remarked, "that the Profession do not believe that infinitesimal doses of medicine have any effect in relieving true disease, whatever supposed effect they may have over imaginary disorders; further, they suspect that many of those who profess to follow the system do not fully carry out their own principles, and are often obliged in serious cases to fall back upon legitimate medicine, and give efficient doses, though in a highly concentrated form. Regarding, then, the system as a delusion, if fully carried out, or as one involving an unworthy deception, if evaded, they do not see how, with any regard to their own honour, they could take part in or sanction such a plan of treatment." With that letter closes the correspondence. He hoped the members had come to the conclusion that he and his friend had acted courteously, but firmly. (Hear, hear.) He should just like to call attention to Mr. Fergusson's letter. Mr. Fergusson stated that he accompanied Dr. Bell to Lincolnshire to see an urgent Surgical case! But he (Dr. Paley) would say that it was scarcely a Surgical case at all, and certainly not an urgent one. In another curious letter from the lady she says, "We did not send for Mr. Fergusson, Dr. Bell brought him;" but the former gentleman says he does not consult with Homœopaths; but if going down to Lincolnshire with Dr. Bell to see a patient, and meeting him and Mr. Jackson at the patient's house, he not consulting, he (Dr. Paley) did not know what was. The circumstance of Mr. Fergusson attending the case with Dr. Bell, had left an impression on the minds of people in the neighbourhood, that Mr. Jackson was justified in so doing. What possible reason was there for bringing Mr. Fergusson down at all? The case must have been extremely exaggerated on the part of some one; but the result of the investigation showed that the case was not of the character represented to Mr. Fergusson. He knew that attempts had been made to produce an impression prejudicial to Mr. Philbrick and himself, who were accused as having acted from pique, whereas they had been actuated by a sense of duty and honour.

Mr. PHILBRICK had nothing to add to the statement of Dr. Paley; and it would only be occupying their time uselessly if he were to make any lengthened observations. He felt that he had to choose between his honour and his pocket, and he preferred retaining his honour. (Applause.)

Dr. WEBSTER said: After these clear and satisfactory statements, I think I shall be justified in proposing for your consideration the following resolution:—"That it is the opinion of this meeting that no honourable man, whether Physician or Surgeon, can meet in consultation a Homœopathic practitioner, or, as such, can act in conjunction with him." The unhappy alliance between Mr. Fergusson and Dr. Bell has called forth several letters, which have found a place in one only, I am sorry to say, of our Medical journals; and after the perusal of those letters in the *Medical Times and Gazette*, the question has arisen in my mind whether our Professional duties to our patients are ever at variance with that proper respect and duty each man owes to himself individually. I do not think they ever are, and I hope to make it appear that if we always entertain a proper appreciation of those duties, they never can be so. If we have no belief in the truth of principles in the acquisition of which we have all spent so many years of study and research, it is full time they were discarded, and some others substituted in their place. But if, to use the words of Dr. Sieveking, "we have the full assurance of the reality of our science, and that we believe what we have learnt, and what we are daily practising," are we true to ourselves, are we just to ourselves, by word or deed to throw into the minds of our patients discredit, diffidence, or disbelief of the remedial agents or measures we prescribe for their ailments? This is not the way to inspire hope and confidence, oftentimes the means of cure, and at all times so essential in the treatment of the sick, to which mental comfort and dietetic injunctions the dogmatic Homœopath can only trust. What, then, becomes of the aphorism in the letter of "Justa aut Nihil?"—"Since Homœopathic remedies are nothing, treat them as nothing, and let your patients take them or not, just as they please." Would this be manifesting a faith, a confidence in your own Medical creed, or be discharging your duty to your patient, in permitting him to rely for the relief of his malady upon means you conscientiously believe to be

worthless? Could you say this to your patient, "Do this, or take this, and it is my honest opinion that you will be better?"

This motion was seconded and carried unanimously.

Dr. BARKER said: Mr. President and Gentlemen,—It is with feelings at the same time of regret and of pleasure that I second this resolution—of regret, because it is necessary to vindicate the honour of our noble Profession against one of the worst forms of heresy which ever crept into it; and of pleasure, because so many of our members are inclined to meet together for the purpose of defending that honour when it has been sadly assailed. In some way the transcendental ravings of a German empiric have, in our day, become fashionable, and have found partisans from among a few renegade members of our own Profession. Many other delusions might be alluded to which sprung up in days of yore, became to a certain extent fashionable and popular, but at length went the way of all other errors and impositions, and are now known only in history. That Homœopathy will follow this course there can be no doubt. It has well nigh died out in the land which gave it birth, and will ere long be found only in the history of great frauds and delusions. Some other form of empiricism will take its place and have its day, and thus there will ever be a contest between truth and error, between the genuine and the counterfeit, between the true student of nature and of science, and the mere worshipper of Mammon. As a Medical system, there is no doubt in the mind of any one who has studied it, that Homœopathy is a great delusion. Every one who practises it belongs to one of only two classes—either he believes it, and is himself deluded; or he does not believe it, and practises it for the sake of deluding others. Now, of the first class, whose mental calibre we will not characterise, there are very few, if any, practitioners. Of the second class, it is to be regretted, there are many. One significant fact we will just notice, *en passant*, that we cannot call to mind a single instance of a man joining the ranks of the Homœopaths who, at the time of his pretended conversion, enjoyed an extensive practice based upon the legitimate system. This looks very suspicious. In fact, it has been adopted by men who have failed to realize their wishes in the regular mode of practice, or as a stepping-stone by young candidates for respectable practice. It is true that some Medical practitioners, and educated men too, seeing that occasionally a respectable patient might be obtained by the concession, have been willing to practise either way; to give the large bolus or the tiny globule; the five-grain dose or the decillionth-of-a-grain dose, according to the choice of the patient! By some practitioners Homœopathy has been adopted in name and form only; for under the pretence of giving infinitesimal doses, they have given the ordinary doses of active medicinal agents. A case came under my notice a short time ago in which mercury had been given by a Homœopath, in such doses as to have produced salivation. In fact, it has been proved that in some cases poisonous overdoses have been surreptitiously given, and the poor patient destroyed. All this undoubtedly indicates a sad want of principle, and the time has arrived when every true lover of his Profession must take his stand against the imposition. The immediate cause of this movement you have already heard very ably stated by Dr. Webster, Dr. Paley, and Mr. Philbrick. A distinguished consulting Surgeon has been tampering with Homœopathy. It is true he repudiates the notion of having consulted with the Homœopath, but the line of demarcation between having been fetched by, and travelling with, the charlatan, and consulting with him and Mr. Jackson in the patient's house, does not appear to have been very broad, distinct, and satisfactory. It is high time that the Profession should cease to treat the subject with apathy. If we in the provinces feel it to be our duty not to soil our hands with quackery, and to forego the fees which are proffered to us from this source, surely it is equally—aye still more—incumbent upon our more distinguished metropolitan brethren, not to yield to the temptation; not to touch "the unclean thing." It is a good sign of the times, that the Medical journals have taken so correct a view of the subject. Some leading articles which have lately appeared deserve to be printed in gold, and placed in the library of every true Medical man. The sentiments which have been so well expressed by the journals, and which have been broached to-day, are those which are entertained by nineteen-twentieths of the Profession. In all probability very many of the Profession feel so strongly on this point, that they would not consult with any one who so far recog-

nised charlatany as to consult with Homœopathic practitioners. I do not hesitate to state that I would refuse, in any case, to meet the Physician or Surgeon who had been known openly and avowedly to have met a Homœopath. The time has arrived when the line must be drawn between the true Profession and the false Profession; between those who boast of their Harvey, Sydenham, Heberden, Jenner, the Hunters, the Coopers, Abernethy, Liston, Brodie, Copland, Bright, Latham, Williams, Watson, Paget, and, though last, not least, Richardson (who favours us with his company to-day), and a host of other bright luminaries, and those who glory in Hahnemann, Holloway, Fleischmann, Coffin, Morrison, Epps, L'Amert, Culverwell, *et hoc genus*. In answer to the question, What should be done? I would just throw out the following suggestions:—1. That every individual member should, in his own conduct, most jealously regard the honour of the entire body. Attention to this fundamental rule would be all that is required. 2. That a central and extensive medico-ethical association should be established for the purpose of framing a code of ethics adapted to the present condition of the Profession. This would also constitute a court of appeal. Several smaller medico-ethical associations exist scattered through the country, the parent of them having been established in Manchester eleven years ago. I wrote to the President of the Manchester Medico-ethical Association, Sir James L. Bardsley, to ascertain if any resolution had been adopted relating to Homœopathy. It appears that the first bye-law of that association declares that "no member shall practise professedly or exclusively Homœopathy, hydropathy, or mesmerism," and in the Code of Etiquette it is declared that "no member shall meet in consultation any medical practitioner who may be inadmissible by the operation of the bye-laws, section first, as a member of this association." Sir James Bardsley adds, "I may say that no member of our association would, under any circumstances, meet in consultation with Homœopaths." 3. That petitions should be forwarded to the heads of Universities and Colleges, urging them to the judicious exercise of all the power they possess. There can be no doubt that the universities and colleges have been apathetic; with one exception, that of the College of Surgeons in Edinburgh, I am not aware that any notice has been taken of the dishonourable conduct of their members. An immense amount of good would accrue from a movement in these quarters. 4. That the editors of the Medical Directories be requested to publish a list by itself of the members of the Profession practising Homœopathy, hydropathy, mesmerism, &c., instead of incorporating them among the true Medical men. 5. That resolutions on the subject be adopted by every meeting of Medical men throughout the country, and forwarded to the medical journals for insertion.

Mr. PAGET congratulated the meeting upon an amended resolution, which was a great improvement on the motion, as it appeared in the circular calling the meeting. But he would even now venture to suggest that it was not sufficiently explanatory of their object. It appeared to him that the resolution should not only embody the sentiments of the Profession, but it should distinctly state the grounds on which they based their opinion. He had drawn up a resolution which he would read to the meeting; it was as follows:—"That so long as a system has no higher philosophy than the jargon of 'similia similibus curantur,' nor sounder chemistry than the delusion of 'infinite dynamization,' it is degrading to a man of education to be connected with it. He, therefore, who assents to consultation with Homœopaths, be they impostors or dupes, forfeits the respect of his Professional brethren, and his membership of this Branch of the British Medical Association." The motion was seconded and carried unanimously.

Mr. MARRIATT said the very honourable conduct of Dr. Paley and Mr. Philbrick was beyond all praise, and demanded an expression of approval from that meeting. He sincerely hoped that the Profession generally would follow their example. He could not but express his very great regret at the annoyance to which they had been subjected. He would move a vote of thanks to those gentlemen for their honourable and straightforward conduct in the matter which had formed the subject of their deliberations to-day.

Dr. WILLIAMS seconded the motion, which was carried unanimously.

Dr. PALEY briefly thanked the members for this cordial

expression of their sympathy. The circumstances had made a strong impression in the neighbourhood; but he was quite sure that all candid persons must admit that he and his friend had honestly performed their duty. (Hear, hear.)

The PRESIDENT alluded to the fact of Mr. Fergusson accompanying Dr. Bell, and suggested whether the meeting would not be justified in passing a resolution on the subject. It appeared there was not the slightest necessity for going to Lincolnshire, and there is no doubt about the consultation.

Mr. PAGET said Mr. Fergusson must have known that Dr. Bell was a Homœopathic practitioner when he accompanied him to Lincolnshire, and yet he said that he does not encourage Homœopaths; but he (Mr. Paget) would say he did give encouragement to consult him; and it was a question whether they ought not to pass a resolution condemnatory of the conduct of Mr. Fergusson, and of the practice of meeting a Homœopath under any circumstances whatever.

Dr. RICHARDSON said Mr. Fergusson, unfortunately, was not the only prominent man who favoured Homœopaths. It was exceedingly distressing to all honourable men; because, if it were not for the countenance Homœopaths received from some members of their own Profession, the public would not be duped in the way they have been. He was sorry that Mr. Fergusson, in his good-natured way, should have allowed himself to attend to the representations of a Homœopath. But if they passed a condemnatory resolution, it would be simply making a martyr of him, while the others would go scot free.

Dr. BARKER said he would give up a patient rather than meet any one who avowedly met Homœopaths. If a man wished him (Dr. Barker) to meet in consultation with another practitioner who encouraged Homœopaths, he should refuse.

The resolutions being carried, it was ultimately agreed that a copy of them should be forwarded to Messrs. Fergusson and Jackson. After receiving the signature of every member present, it was also agreed that the resolutions should be sent to the absent members of the branch for their signatures, and then forwarded for insertion in the weekly Medical Journals.

#### LETTER FROM MR. GEORGE HORNBY.

[To the Editor of the Medical Times and Gazette.]

SIR,—I beg to forward you for insertion in your Journal a copy of some resolutions passed at a large and influential meeting of the Yorkshire Branch of the Medical Association, held at Leeds on the 27th instant:—

Proposed by Mr. Teale, and seconded by Dr. Swaine, and unanimously resolved,—“That the members of this branch pledge themselves neither to meet in consultation, nor attend in conjunction with Homœopathic practitioners.”

Proposed by Mr. H. Jackson, and seconded by Mr. Husband, and unanimously resolved,—“That no member of this branch will meet in consultation any member of the Profession who knowingly violates the last resolution.”

I am, &c. GEORGE HORNBY,

York, May 31, 1858.

Hon. Sec.

#### ROYAL MEDICAL BENEVOLENT COLLEGE.

##### STATEMENT OF THE DISSENTIENT GOVERNORS.

I.—That in 1855 the Council of the Royal Medical Benevolent College, without fully consulting the governors, obtained an “Act of Incorporation,” the provisions of which were such as to preclude the subscribers from an effective control over the management of the College.

II.—That, by virtue of the powers thus reserved to itself, the Council has:—1st, improvidently administered the funds committed to its charge; 2ndly, misapplied moneys subscribed for special purposes; and, 3rdly, unjustly deprived the sons of living Medical men of restricted income of the cheap education originally promised.

##### 1. Extravagance and Mismanagement:—

a. The estimated cost of the buildings was £18,000. For this money there were to have been residences for 104 pensioners, accommodation for 100 scholars, and a chapel. The architect's plan, which is very simple, and has not been materially departed from, is not yet com-

pleted, although more than £36,000 have been expended in building purposes(a).

b. The law expenses alone up to 1856 amounted to £1789, exclusive of the cost of the "Act of Incorporation."

c. The architect, whose commission on his original estimate (at 5 per cent.) would have been £900, has already received, on account, the large sum of £1600.

d. The Council has received upwards of £50,000 in subscriptions and donations. Out of that sum only £2500 have been expended in the education of free scholars, and only £193 (!) in grants to resident pensioners. Nevertheless, the Council has already mortgaged the land and buildings for £7000. The pensioners received in 1856 only £5 each, and in 1857 only £10 each, without any further allowance for servant, board, or clothing.

e. That the Council managed the funds entrusted to its care so as to sustain a loss of £1169 on its investments.

## 2. Misapplication of Special Funds:—

a. In accordance with the 6th clause of the Act of Incorporation, the Surrey Benevolent Medical Society paid £2000 to the "Endowment Fund" of the college, to secure certain privileges to four scholars. The Council, instead of funding the £2000, as they were bound to do by their 9th bye-law, employed it for other purposes. Other moneys were subscribed, especially to the "Endowment Fund," yet no Endowment Fund was founded with those sums.

b. £2760 were specially subscribed to build a chapel. In December, 1856, only £150 had been devoted to this object, the remainder had been otherwise spent.

## 3. Unjust increase of charge to paying Scholars, so-called Exhibitioners:—

a. By the original prospectus, a first-class education was promised to the sons of Medical men for £25. This was an original feature of the scheme. It was to be a boon, not to the rich, for they could not need it, but to those who were unable to pay for their sons the ordinary cost of a good education. These scholars were termed "Exhibitioners," and the Council were charged with the duty of selecting those entitled to benefit by the boon. This charge, when the school opened, had been raised to £30, including the use of books.

b. When the boys (who had been removed from other schools) had been at the college for nearly a year, the charge was raised to £40, and enforced against the boys already in the institution.

The dissentients to these acts of the Council leave the evidence of mismanagement, extravagance, and misapplication of funds to speak for itself. The Council up to the present moment has made no reply to the charges against it on these heads, except by asserting in its report the flourishing state of the college. The matter of the school, however, has been replied to. We briefly state the arguments on the two sides.

### Council.

That the Act of Incorporation, clause 38, forbids the application of any portion of the funds of the college to assist in the maintenance and education of paying scholars—sons of Medical men, so-called Exhibitioners. They are supported in this interpretation of the act by the opinion of Mr. Freshfield (a member of the Council), and by that of Mr. Willcock, whose opinion was taken after the charge had been increased.

### Dissentient Governors.

That the 38th clause of the Act of Incorporation does not forbid the application of a portion of the funds of the college, if necessary, to assist in maintaining and educating Exhibitioners; because this cheap high-class education to the sons of needy Medical men is one of the main objects of the foundation, being prominently put forward in the original prospectus, as well as in that issued after the act was passed, and also because the act must not (as a private act) be so interpreted as to involve a compulsory alteration in the plan and laws of the institution, which existed at the time of the passing of the act, and upon the faith of

which the public had subscribed their money. The Dissentient Governors are supported by the opinion of Messrs. Frere and Co., and also of Mr. Roundell Palmer. The case submitted to Mr. Palmer has been published.

That under good management the *prime cost* would not exceed £30.

That, in the estimate of the Council, there are charges which are unreasonable and exorbitant, viz.:—

Office Expenses to the extent of £238 10s. per annum for 150 boys.

A charge for wear and tear of furniture, and fittings, and of linen, to the extent of £712 2s. per annum for 150 scholars.

Extravagant expenditure in the domestic arrangements of the school as compared with other similar establishments for the sons of Professional men.

3. The dissentient Governors further complain of the unfair conduct of the authorities of the College in the following particulars:—

1st. At the Extraordinary Meeting, April 3, 1857, convened by requisition, signed by 147 Governors, to consider the increased charge to exhibitioners, and other important business, John Labouchere, Esq., in the chair, fair and full discussion was suppressed, and the meeting was broken up without completing the business for which it was called. Prior to this meeting a letter calculated to prejudice the Governors was circulated by the Treasurer.

2nd. At the Annual General Meeting, 1857, it was ordered by the Meeting that "a balance sheet of the accounts of the College, from the beginning of the undertaking till December 31, 1856, be printed and circulated," with a view to exhibit the liabilities and assets of the College. *This order has been disregarded*; a mere divided and obscure statement of the receipts and expenditure, not showing the liabilities, was substituted by the Council.

3rd. At the Annual General Meeting, held May 11, 1858, John Labouchere, Esq., having been again placed in the chair, discussion was a second time completely stifled, and the Meeting conducted with such partiality as to draw forth a protest even from adherents of the Council. Prior to this Meeting the Treasurer again addressed a letter to many Governors calculated to influence an important election. (See Report in *Morning Post*, May 13, 1858, and *Morning Herald*, May 12 and 14, 1858.)

Signed on behalf of the Committee,

June 1, 1858.

WM. CHOLMELEY, M.D. Hon. Sec.

## LETTER FROM MR. JOHN PROPERT.

[To the Editor of the Medical Times and Gazette.]

SIR,—Certain letters having been published in the Medical journals in reference to the affairs of the Royal Medical Benevolent College, which I cannot but think may, to some extent, mislead those of the Governors who have not inquired into the facts of the case, I trust you will allow me as briefly as possible, and once for all, to reply to them. The allegations of mismanagement on the part of the Council, appear to be founded on certain statements which were diligently circulated among the friends of the Institution some months ago, in the form of a pamphlet, entitled a "Report of a Sub-Committee of Governors," "the avowed object of which Report was to support the interests of the exhibitioners of the College." By pointing out to your readers the errors and mis-statements of this pamphlet, I shall, I trust, remove from all reasonable minds any unhappy impression that it may have produced

(a) The Scholastic Department proper accommodates 110 boys, but, on the other hand, there are residences provided for only 20 pensioners.

The charges therein brought against the proceedings of the Council may be briefly comprehended under four heads, namely,—“extravagant outlay,”—“misapplication of funds,”—“obtaining inordinate power by procuring an act of Parliament for the purpose of depriving the exhibitors of a cheap education,”—and “extravagance in the board and education of the exhibitors.”

1. With regard to the first of these charges,—extravagant outlay in the building and arrangements of the College—I have only to say that, whereas in the pamphlet it is stated that the building cost £45,000, the fact is that the cost, including that of the chapel, was only £35,000. Here, then, is a fundamental error of ten thousand pounds at the outset, and this is, I grieve to say, but a sample of the rest. As to the outlay exceeding the original estimate,—this was rendered unavoidable by the extraordinary rise in the price of labour and materials, and by many other unforeseen difficulties, which intervened between the period when the estimate was made and that in which the building was commenced; to which may be added, that the state of the funds seemed to justify the Council in providing a third room for the accommodation of the pensioners.

2. The second charge, that of misapplication of funds, is equally unfounded; the grounds of this allegation are only apparent, not real, and have arisen from an economical arrangement which could not be explained in the balance-sheet, but which was fully explained in the report read to the Governors at the last annual meeting.

3. The third charge is also founded on misrepresentation and error; the Council did not obtain *inordinate power*, by procuring an Act of Parliament for the purpose of depriving the exhibitors of a cheap education. On the contrary, they *lost* the power of carrying out their original intention and most earnest wish of providing a first-rate education for the sons of Medical men, at £30 per annum; and they lost it, not by any act of their own, but by an Act of Parliament which was *forced upon them much against their will*. This also was fully explained by Mr. Freshfield at the annual meeting of Governors.

4th, and lastly; the charge of excessive outlay in the board and education of the exhibitors, which charge, it is attempted to prove by figures, is also utterly unfounded. The attempt to show that the expenses of a school at Epsom can be easily reduced to the sum required for a certain school at about one-eighth of the distance from the London markets, is preposterous: and the proposal to reduce the expenses by such petty suicidal economy as abolishing the London Offices, making no charge for wear and tear of fittings, charging the Charitable Fund with the whole of the Headmaster's fees as Chaplain, and with the insurance of the school furniture (which last item would save each exhibitor the heavy expense of tenpence per annum);—these and similar suggestions gravely proposed in the pamphlet, but too plainly show that the search for grievances is desperate, and that the animus of the malcontents is not such as to entitle their representations to any great amount of respect. Having thus replied to the charges which have been brought against the Council, I may be allowed to ask, on what are these objectors intent? If they indulge a vain and frantic wish to pull down this noble edifice about their ears, I can understand their proceedings; if not, I ask, *what possible good, and how it will, can this factious opposition effect?*

New Cavendish-street.

I am, &c.

JOHN PROBERT.

## MEDICAL INSTITUTION OF LIVERPOOL.

A special meeting of the members was held at their rooms, Mount Pleasant, on Tuesday evening, May 25, for the purpose of considering the propriety of again addressing the committees of the public charities of Liverpool, on the subject of the present mode of conducting the election of their honorary medical officers, whereby a canvass personally or by the active agency of friends is rendered necessary; a proceeding which is considered by the Profession to place them in a false and undignified position.

The chair was taken by Dr. MACINTYRE, Vice-President of the Institution.

Mr. DESMOND moved the first resolution, briefly stating the

circumstances that led to the present movement, which commenced in 1856, when an address was forwarded to all the public charities of the town, and the recommendations of the Profession were acted upon by the Southern Hospital, and more recently by the St. Anne's Dispensary. To illustrate how harassing it must be to the Trustees to exercise their privilege of voting, even after being canvassed, Mr. Desmond alluded to the fact, that at the last two elections for honorary Surgeons to the Liverpool Dispensaries, out of 1200 Governors who were entitled to vote, there polled at the election in September, 1856, for the first candidate, only 36; for the second, 26, and for the third, 15 votes; and at the election in April, 1857, the votes were, for the first candidate, 56, and for the second, 36.

Resolution I.—“That this meeting views with much satisfaction the alterations made by some of the Public Charities, whereby the election of Honorary Medical Officers is for the future to be carried on without canvassing; but it has also to regret that this mode of election has not been more generally adopted.”

This Resolution was seconded by Dr. Cameron, and having been put to the Meeting, was carried by acclamation.

Dr. Voss stated, that having held office in several public Institutions, he could bear testimony to the undignified and false position in which Medical men were placed, when forced to canvass with the view of obtaining an appointment; and he considered that this mode of election gave an overwhelming advantage to those candidates who had numerous friends, and irrespectively of their Professional abilities. He felt great pleasure in submitting to the Meeting the following Resolution:—

Resolution II.—“That our Secretary be requested again to call the attention of the Committees of the Public Charities, to the letter from the Institution, dated April 21, 1856, and once more to urge upon them the desirableness of making such alterations in the present mode of electing their Medical Officers, as will effectually put a stop to canvassing, and meet the wishes of the Medical Profession.”

This Resolution was seconded by Dr. Imlach, who had been a member of the original committee appointed to consider this question. He assured the Meeting that he felt warmly interested in the success of the present movement.

Several members expressed similar sentiments in support of the Resolution, which having been put to the Meeting, was carried by acclamation.

Dr. DICKINSON moved the next Resolution.

Resolution III.—“That the thanks of this Meeting be conveyed to the Governors of the Southern Hospital, and of St. Anne's Dispensary, for having so far acted in conformity with the suggestions of the Profession.”

He regretted that he had been unavoidably absent from town when this important question had been brought under the consideration of the Profession, and added that his personal experience had convinced him of the great objections to the system of canvassing for public Medical appointments. The alterations adopted by the Southern Hospital and the St. Anne's Dispensary met with his cordial approval, and deserved the best thanks of the Profession.

The motion was seconded by Mr. GRIMSDALL, who impressed upon the Meeting the necessity of individual exertion on the part of all those who already held appointments in any of the Medical charities of the town, with the view of urging the Trustees to take this subject into consideration.

The resolution was then put by the Chairman, and carried unanimously.

After a few remarks by some of the members, and the usual vote of thanks to the Chairman, the meeting separated.

(Copy of letter alluded to in Resolution II.)

“Medical Institution, April 21, 1856.

“SIR,—At a special meeting of the members of the Medical Institution, held on the 10th instant, it was unanimously resolved,

“‘That in the opinion of this Society, the present mode of electing honorary Medical officers to public charities, and the canvassing consequent thereon, are highly objectionable, being derogatory to the dignity of the Profession, and harassing to the Trustees.’

“Dr. Voss, Dr. Macintyre, Dr. Fergusson, Mr. Long, and Dr. Imlach were appointed a committee to carry out the views

of the Meeting; and they are desirous of ascertaining whether your committee sympathises with this movement, as they then hope to be able to propose a plan by which all canvassing, whether by personal application, by circular, or by advertisement, may be avoided.

"I have the honour to be,

"Sir, your obedient servant,

"H. IMLACH, Sec. to the Committee."

## REVIEWS.

*Observations on Naval Hygiene and Scurvy, more particularly as the latter appeared during a Polar Voyage.* By ALEX. ARMSTRONG, M.D., R.N. Pp. 117. London. 1858.

Dr. Armstrong is already favourably known to the Profession and the public by his *Personal Narrative of the Discovery of the North-West Passage*, published last year, and reviewed in our columns. In that very graphic history, Dr. Armstrong made known the perils and dangers, the hardships and privations, which many of our brave countrymen endured while engaged in the arduous duties which nearly terminated their own lives, but which were rewarded by the important geographical discovery so long and so earnestly sought for. In the present work Dr. Armstrong has devoted himself to a subject exclusively medical; namely, the Pathology and Treatment of Scurvy; and in connexion with this disease he has offered some very useful observations upon Naval Hygiene in general.

The opinion that scurvy might be prevented altogether on ship-board by the adoption of sound hygienic measures, appears to be fully borne out by the experience gained during the voyage of the Investigator; for it was not until upwards of two years and three months from the date of the ship's commission, and after a residence of two winters in the ice, during the second of which the crew were on short diet, that scurvy made its appearance. After the period alluded to, when the crew were reduced by hard work, privation, and despondency, the disease at last supervened; and, from the necessary absence of remedial appliances in the desolate regions of the Pole, several of the sailors were carried off. The melancholy spectacle of the illness and death of many of the crew from well-known though, under the circumstances, unavoidable causes, necessarily gave Dr. Armstrong peculiar opportunities for observing the symptoms and varieties presented by scurvy; and he has turned the materials thus placed at his disposal to good account.

He confirms the impression generally entertained that a long-continued use of salt meat is the chief cause of scurvy; and he recommends that less salt should be employed in preserving the meat, and that spices should be substituted to a certain extent. While admitting also that the quality of the salt meat now supplied to the navy is much better than it was in former times, he tells us that it is not yet always so good as it might be, and that he has occasionally seen salt beef so hard that it resembled the consistence of wood, and was actually fashioned sometimes into ornaments by the sailors.

The remedial treatment of Scurvy consists in the administration of lemon-juice: a fluid which is very properly ordered to be used on board all sea-going ships, but which, in the merchant service, is certainly not so extensively or so regularly given as it ought to be. Dr. Armstrong, also, very properly insists that it should not only be given to the men, but that proper regulations should be observed to ensure their drinking it; because any neglect in its administration or its consumption may lead to the establishment of a cachectic debility which may terminate in an outbreak of confirmed disease.

The view advanced by Dr. Garrod, that the beneficial effect of lemon-juice in scurvy may be due to the potash contained in the juice, and not to the acids, finds no favour with Dr. Armstrong, who denounces any alkaline treatment as altogether inefficacious, and, indeed, positively detrimental. He considers that the vegetable acids contained in lemon-juice possess some specific power over scurvy, and that the combination of acids in the juice, namely, the citric and the malic, possesses more efficacy than the citric alone, although the latter is a very good, and indeed the best substitute, for the lemon-juice itself.

As a record of personal experience in a very terrible disease, but one which is certainly under the control of medicine, Dr. Armstrong's book will be read with the highest interest; while the numerous remarks on Hygiene, in which it abounds, are well worthy the careful attention of the authorities to whom is intrusted the superintendence of the lives and health of our marines, whether in the navy or the merchant service, in every region of the globe.

*Mémoire sur l'Anatomie Pathologique des Rétrécissements de l'Urèthre.* Par JOSE PRO, M.D. Paris, 1856, Leclerc.

*A Memoir on the Pathological Anatomy of Strictures of the Urethra.* By Dr. JOSE PRO. Paris, 1856, Leclerc.

One of the most remarkable instances of wholesale plagiarism which it has been our lot to meet with for many years occurs in a work, the title of which is placed above. It is difficult to say whether the extent of the theft, or the unscrupulous and barefaced manner in which it has been performed, is the more striking peculiarity of the performance.

The work commences with introductory matter, containing a brief account of the anatomy of the urethra, and an imperfect history of English and French literature relating to the subject. At the close of this, the author offers the results of "his own proper observations," in relation to the pathological anatomy of stricture, and this he terms "the body of the work." This "body" comprises twenty-six quarto pages. Will our readers believe that *twenty-three of these pages* are rendered almost *verbatim* into French from the well-known work on that subject by Mr. Henry Thompson? Yet such is the fact: Dr. Pro has laid under contribution nearly the whole of the second chapter in that work, simply translating with very considerable care and accuracy page after page, as it appears in the English. No acknowledgment whatever is made; and although Mr. Thompson is named, all allusion to his authorship is studiously avoided.

What makes the appropriation worse is, that the book before us was in the first place sent to the Société de Chirurgie of Paris as an original memoir; and the consequence was that the thanks of the Society, and the title of Corresponding Member, were conferred upon its presumed author for the pathological researches he was supposed to have made. As an example of the manner in which the whole is executed we subjoin the following passage:—

MR. THOMPSON, p. 59.

"On laying open a strictured urethra after death, we shall discover that the structure in which the constriction itself is seated, is by no means always the same. It may be almost confined to the mucous membrane of the urethra, in which case it, as well as the bundles of elastic fibre beneath, appear to be simply hypertrophied, a condition which may be regarded as the primary and most elementary form of stricture; and the narrowing usually disappears when the section is made, leaving, perhaps, only a faint white line or two by which to indicate its situation. There is no particular redness of the membrane, &c."

DR. JOSE PRO, p. 51.

"Quand, à l'autopsie, on ouvre un urèthre rétréci, on remarque que la structure du rétrécissement n'est pas toujours la même: elle peut être limitée à la muqueuse de l'urèthre, et, dans ce cas, il y a une simple hypertrophie de cette membrane aussi bien que des faisceaux de fibres élastiques sous-jacents. Cet état de choses peut être regardé comme une forme de rétrécissement primitif et élémentaire, rétrécissement qui disparaît ordinairement après la section, ne laissant d'autre trace de sa présence qu'une ou deux lignes blanchâtres. On n'observe pas de rougeur particulière de la membrane, &c."

And thus the translation is continued, sentence following sentence, and paragraph paragraph, to page 73, where the original matter ceases, and the remaining portion, consisting of quotations from the printed catalogues of our metropolitan museums, commences. These are appended as illustrations of the pathological observations recorded in the body of the work.

We have felt it to be a duty we owe to literature in general and to our English author in particular, to expose this scandalous appropriation of his researches. Such conduct can indeed be only truly characterised in the terms of a criminal indictment.

## PROGRESS OF MEDICAL SCIENCE.

### Selections from Foreign Journals.

#### ON INCISION OF THE OS UTERI DURING LABOUR.

By Dr. KRISTELLER.

Dr. Kristeller has had occasion to perform this operation in ten instances, and, in a paper read at the Berlin Midwifery Society, he states that the general conclusion he arrives at is, that incision of the rigid os uteri, performed at the proper time and place, is a means for which ipecacuanha, opium, chloroform, ointments or douches do not supply a substitute. Rapid and gentle in its action, it is a far less dangerous operation than authors have considered it, and does not merit the neglect with which it is treated.

The objections that have been made to it are the following : 1. It has been feared that the irritation of a wound occurring in the usually highly excited condition of the woman, might, from the sympathetic action of the nervous centres, give rise to convulsive paroxysms. The author's experience has, however, shown him that hardly any sensation of pain is produced, and that reflex convulsions are never excited. On the contrary, the previous excitement and perverted activity of the nervous system, upon the supervention of effectual pains, disappear. Such nervous phenomena are much oftener the result of fruitless parturient efforts, owing to the extension and laceration the sensitive vaginal portion undergoes, and the pressure it is submitted to between the child's head and the pelvic walls. The incision puts an end to this condition in the most rapid and most easy manner. 2. A too precipitate birth has also been feared, together with its ill consequences, and especially the extension of the section by rupture into a higher portion of the uterus. The author has certainly observed in most of his cases a rapid termination of the labour, but this has been unaccompanied by any danger or any extension of the wound of the incision. The acceleration of labour is indeed only apparent. In the cases in which the operation is indicated, the labour has continued for hours or rather for days, the vagina and external parts are usually soft and distended, the head, covered by the thinned vaginal portion of the cervix, has to a certain extent descended into the pelvic cavity, and the anterior wall of the uterus is drawn downwards—so that the rigidity of the os uteri forms the only obstacle to an early delivery. If the labour, by the removal of this, is enabled to take on a rapid course, the muscular contractility of the vagina and external parts prevent this being precipitate, unless indeed there is relatively too large a diameter of the exit of the pelvis. The disposition of the muscular fibres of the neck and vaginal portion of the uterus oppose an obstacle to the further extension of the wound, just as it prevents the increase in the lacerations which are observed in primiparæ. 3. Hæmorrhage is the accident that is most feared; but the author only met with it in one of his cases, in which the lip of the uterus, in consequence of the prolonged pressure it had been subjected to, had become inflamed, and after incision yielded about 12 ounces of blood. The bleeding was arrested first by vinegar and water, and then by the progress of the labour. The rigid os is usually indurated, unyielding, and almost bloodless upon incision.

The operation is indicated when pathological change of texture or the perverted nervous action of the vaginal portion of the uterus obstinately prevents the progressive dilatation of the os uteri, notwithstanding the active character of the pains. To this condition appertains the parchment-like toughness and density of the vaginal portion sometimes met with in old primiparæ, the hypertrophied, fibrous and cartilaginous state left by former inflammatory processes, fibroid formations, cancerous infiltration, and a spasmodic contraction of the os uteri. It need not be stated that so long as no danger is present we must wait with great patience the efforts of nature, apparently irremovable indurations occurring in pregnancy or labour often yielding to her great solvent power. So, too, must the various milder internal and external measures be tried before resorting to incision. The author has indeed derived little advantage from the patient employment of mucilaginous and oleaginous frictions, ointments, injections, or baths: and opium, bleeding, chloroform, belladonna oint-

ment, and the warm douche have by no means always proved successful. The douche is, however, next to incision, the most useful measure: but it is not to be lost sight of, that its too diligent employment endangers the life of the child.

To recapitulate: judging from his own experience, Dr. Kristeller regards incision in these cases as an imitation of nature's own procedure in primiparæ, and he considers that the operation is often omitted to the great disadvantage of the patient. It is an operation without danger, of easy performance, gives rapid relief to present suffering, and wards off threatening dangers, as rupture of the uterus, convulsive paroxysms, etc.: and there is more danger in performing it too late than too early. In the performance of the operation he employs a curved, pointed bistoury, which, guarded by sticking-plaster to within three-quarters of an inch of its extremity, is passed in between the child's head and the vaginal portion, penetrating the latter at about half-an-inch from the margin of the os uteri. The knife is then drawn rapidly inwards and downwards. Three or four such incisions usually suffice, and these should be made quickly after each other.—*Monatschrift für Geburtskunde*, Band x. pp. 163—168.

#### EXCERPTA MINORA.

*Nitrate of Silver in Ascarides*.—Dr. Schultz states that he has employed enemata of this substance with great success for the removal of the *oxyuris vermicularis* which so frequently infests the anus in such large numbers. The clyster is formed of argent. nitrat. gr. x. ad xv. to aq., dest. ʒiv. Two, or at most three, of these suffice to effect a complete cure. The first one does not usually remain up long, and worms, some living and others dead, are returned with it. The next clyster remains from six to twenty-four hours, and the great mass of the dead worms are discharged with it.—*Deutsche Klinik*, No. 17.

*Blistering in Zona*.—M. Hervé de Chégoin observed in a recent discussion that he had derived great advantage from the application of blisters in zona, these promptly relieving the suffering when applied to the spots where the vesicles threaten to appear. Should the neuralgic pain accompanying this affection not yield, morphia might then be employed endermically.—*Bulletin de Thérap.* May, p. 432.

*Amaurosis from large doses of Quinine*.—It has been long known that large doses of quinine not unfrequently give rise to deafness or other perversion of the organ of hearing; and Professor A. v. Gräfe now states that he has met with two cases of amaurosis produced by the same cause. In the one case the patient took half dram doses daily for some time, taking altogether ʒvj. of quinine, and in the other case taking altogether ʒj. He chiefly relies on local depletion for its relief.—*Archiv. für Ophthalmol.* Band iii. p. 396.

#### GENERAL CORRESPONDENCE.

##### CAUSE OF HYPERTROPHY OF THE HEART.

LETTER FROM J. H. JAMES, Esq.

(To the Editor of the Medical Times and Gazette.)

SIR,—In a lecture which appeared in the *Medical Times and Gazette* for March 13, 1868, by Dr. Geo. Johnson, on "Diseases of the Kidney," I saw the following passage:—"One circumstance in this case to which I beg to direct your attention, is the hypertrophy of the heart, and especially of the left ventricle, without the co-existence of any disease of the valves or of the large arteries, such as would impede the flow of blood, and so explain the increased bulk and strength of the muscular walls of the heart. In a very large proportion of cases of chronic Bright's disease, you will find this hypertrophy of the heart; sometimes associated with such disease of the valves or of the large arteries as may be considered sufficient to explain the phenomena; but not unfrequently, as was long since pointed out by Dr. Bright himself, there is no apparent cause for the marked hypertrophy generally affecting the left ventricle. The most probable explanation of this remarkable fact is, that the blood, being contaminated by excrementitious materials in consequence of degeneration of the kidney, is impeded in its passage through the minute systemic vessels; the left ventricle, therefore, has to make

unusual efforts to propel the blood, and in so doing, it acquires an increase of bulk and strength." Now, Sir, permit me to trespass on your pages for a short statement as regards my own claims, in advancing the theory of obstruction in the minute vessels, as a cause of hypertrophy of the left ventricle of the heart, as they appear to have escaped the notice of Dr. Bright and Dr. Johnson. With respect to the final cause of such obstruction being the contamination of the blood by the retention of excrementitious materials, I offer no further observation, than that, when supported by such authority, the opinion is entitled to every attention; but with reference to obstruction of the minute vessels being a frequent, perhaps the most frequent, cause of hypertrophy of the left ventricle, the following extracts from a paper which I wrote more than forty years ago, which was presented by my lamented master, Mr. Abernethy, to the Medico-Chirurgical Society, and was by them published in the eighth volume of their Transactions (a), will show that, although I did not consider myself as having originated the theory, yet that I supported it by arguments, both physiological and pathological, which I then believed, and do now, to be original. No modern pathologist had then advanced the doctrine of obstruction in the minute vessels being the cause of hypertrophy, not even Corvisart; but Senac had, and I mentioned the fact.

After stating the common opinion, that, when there was mechanical obstruction at the orifices of any of the cavities, dilatation of that cavity and hypertrophy, (as it has since been called,) would ensue, I gave three cases, in which there appeared evidence of obstruction at more remote points, but in the great vessels; and subsequently others, in which a presumption arose that there was obstruction in the minute vessels; and I select the following extracts as explanatory of my views on this matter.

P. 451. "It will be observed in this case (Case 4), as it may in several others, that there is much stronger evidence of obstruction in the passage of the blood through the vessels, than from the heart." I then proceeded to argue, that the minute vessels make the demand according to their wants; that the arteries enlarge or contract, to regulate the supply; and that the heart is merely the reservoir from which this supply is obtained. Pp. 452-3-5. Taking this ground for the minute vessels, the following passages will show how I applied it. After narrating another case (5th) in much detail, the following occurs:—"In this case there was evidence during life as well as after death" (from the state of the organs) "of augmented force of the action of the heart, and undue (b) distension of the arterial system. Analogy would lead us to suppose that it proceeded from obstruction, but there was no organic alteration of structure about the heart itself likely to produce it; and it is therefore fair to suppose that the obstruction was situated in the minute vessels, of a very different nature, perhaps, from that which existed in the case last related."

Referring still to this case, I proceeded to say:—

P. 459. "Was the ossification and disease of the aorta an idiopathic disease of the vessels, or was it produced by the increased actions of the vascular system? This disease is so common a concomitant of active (c) aneurism that it is difficult to avoid supposing it to be either a cause or an effect; but if the former, i.e. if it be idiopathic, why does it not as often occur in the pulmonary artery? If it be considered as a consequence of the disease of the heart, this difficulty is easily explained, because that disease is found on the left side more frequently than on the right, in the same proportion probably, as disease of the artery which leads from it. If we should be able to explain hereafter, how it happens that disease of the heart so much more frequently occurs on the left side, then we may at the same time account for the ossification of the systemic artery being so much more general.

"Where there is enlargement of the ventricle, and augmented strength of pulsation during life, increased capacity and strength of the arteries is found to exist after death, especially if the case has been one of long standing; and

also, very commonly, ossification and steatomatous thickening. That the artery should be enlarged in the same proportion as the ventricle, seems natural enough, and also that its parietes should be thicker, since it has to sustain the impetus of a larger column of blood, impelled with preternatural force; but if there be a difficulty opposed to the arteries in emptying themselves of their contents, which I imagine to be the case, it will follow that the vessels which are now immediately in the neighbourhood of the principal trunk, will have, more especially, the blood forced into them with undue violence, and this will be very likely to occasion unhealthy deposit in the parts so supplied. The vasa vasorum will be particularly exposed to this cause of derangement."

"The coronary arteries in this case, as in most of a similar nature, were also greatly enlarged. If we suppose obstruction to the passage of the blood at the extremity of the arterial system, the resistance would of course throw back the blood to the heart, more particularly, as being the other end of the column; but at the orifice of the aorta, valves are interposed to prevent the reflux. In addition, then, to the first and natural impulse, caused by the action of the heart, there will be the reaction occasioned by the obstruction, and the effects of this will be more felt near that viscus. It is not therefore to be wondered at, that the coronary arteries are found to participate in an eminent degree in the alteration produced by this state."—Pp. 459—461.

I then proceed to follow up the argument by referring to the state of the aortic valves and aorta, thus:—

"There is, however, another alteration of structure, on which I should wish to make a few observations; namely, disease of the valves of the aorta, which is very commonly found where there is any ossification of that vessel, and which is generally believed to be a frequent cause of aneurism of the heart."

"In the first place, it must be observed that these valves, when ossified to such an extent as to afford obstruction to the exit of blood from the ventricle, are commonly found raised and not parallel to the sides of the vessel, as might have been expected *a priori*, considering the current of blood flowing through them from an enlarged heart. This peculiarity it is difficult to explain; but one mode of doing so would be, to offer as a solution of this phenomenon, obstruction situated at the extremity of the arterial system, the influence of the reflux determining their position."

"In the second place, I have to state that in the great majority of instances where ossification of the valves is found, the calibre of the aorta is also greatly enlarged. Now the obstruction thus situated at the orifice of the ventricle, should, if it were the primary disease, by diminishing the stream of blood, have caused rather a diminution of the vessel. But if we suppose dilatation and disease of the vessel first induced, and this disease the ossification which makes the valves rigid; then there can be no difficulty in explaining, what is often found, an aorta of a preternaturally large diameter, when the aperture left by the valves would scarcely permit a quill to pass."—Pp. 461, 2.

The cause or causes of this obstruction in the minute vessels, I next approached; but without encumbering this communication with matter, which after all, whether ill or well founded, are not like the preceding, facts on which I had a right to argue, but which are in themselves hypothetical, I shall give the following extract, which is not of that character:—

"Whatever will fill the larger vessels will distend the heart; and therefore, if these be kept in a state of plethora from any cause such distension of the heart will be the effect; but plethora of the large vessels is not likely to be permanent when the minute vessels are in a healthy state."—P. 476.

The concluding passage (p. 488) bears also upon the pathological condition of the left auricle as contrasted with the ventricle.

In conclusion, I may observe, that although more than forty years have passed since this memoir was written, and great labour has been bestowed on the pathology of the circulating system, especially of the heart, nothing that I am aware of has occurred to invalidate the arguments which I have advanced, grounded on certain pathological facts; neither has the theory I supported upon these facts been invalidated. On the causes of the supposed obstruction I offered no opinion. But that since advanced in the passage quoted from Dr.

(a) Some Cases of Disease of the Heart, with an Inquiry into their Nature and Causes, communicated by Mr. Abernethy, read June 10, 1817.

(b) In the memoir this is printed 'under distension,' which is more nonsense. I unfortunately had not the sheet sent me to correct, and the whole type is full of misprints.

(c) The term Hypertrophy has been since substituted for the "active aneurism" of Corvisart.

Johnson's lecture, is calculated to give additional weight to it; and the coincident support of such pathologists as Dr. Bright and Dr. Johnson is important. Absolute proof of the theory will be difficult; and the undoubted frequency of hypertrophy of the left ventricle, apparently from other causes, has always proved an obstacle to my pursuing the subject further. I may, however, observe, with respect to this important point, that although hypertrophy of the heart often owes its origin to inflammation of the membranes, blows, strains, nervous emotions, etc., yet it is not easy to explain how it is that the systemic ventricle is the part so especially affected; still less, that while increased nutrition is the essence of hypertrophy, there is not one of the causes above enumerated which does not generally tend to produce it.

I am, &c.

J. H. JAMES.

Exeter, March 19, 1858.

### PETITION OF THE COLLEGE OF PHYSICIANS AGAINST THE MEDICAL BILLS NOW BEFORE PARLIAMENT.

*To the Honourable the Commons of the United Kingdom of Great Britain and Ireland in Parliament assembled,*

The humble Petition of the President and College or Commonalty of the Faculty of Physic in London, under their Common Seal,

SHEWETH,

That your petitioners are informed that no less than three Medical Bills are now before your Honourable House, every one of which will, in the opinion of your petitioners, both fail in some instances to remove evils which have long and justly been complained of, and will in others introduce evils worse than those which it removes.

That the Bill "To alter and amend the Laws regulating the Medical Profession," brought in by Lord Elcho, Mr. Fitzroy, and Mr. Craufurd, will destroy the machinery which now exists for testing the education and competency of Medical Practitioners, and will substitute for it a system open to the great objection of establishing a minimum standard of qualification, which will be accepted, nevertheless, as sufficient for every kind of practice, whereby too little inducement will be left to seek qualifications of a higher order.

That the Bill "To regulate the qualifications of Practitioners in Medicine and Surgery," brought in by Mr. Cowper, Mr. Kinnaird, and Mr. Brady, will perpetuate one of the worst evils from which Medical education at present suffers, viz.—That the number of examining and licensing bodies is much too great. That all of these bodies are, by this Bill, to be represented in a Council having not merely administrative power, such as might safely be entrusted to a Representative Council for the purpose of carrying out principles established in the Bill, but having power to make Orders and Regulations as to questions which the Bill itself should decide, relative to the construction of Examining Boards, the assignment of their privileges, and the discipline and government of the whole Profession.

That a Council possessed of powers so extensive, representing at the same time so many conflicting interests, and composed of Members sent from localities so distant and wide apart, will be far more likely to keep the Profession in an unsettled and agitated state, than to promote its peace and permanent good order.

That by the Bill "To define the rights of the Members of the Medical Profession, and to protect the public from the abuses of Medical Corporations," brought in by Mr. Thomas Duncombe and Mr. Butler, all persons possessing any kind of Medical or Surgical qualification, whatever may have been their education and studies, and whatever, therefore, may be the nature and value of their Diplomas or Licences, will be allowed to be registered alike, and to practise as they shall choose in any branch of the Profession.

That if it were proposed that every person possessing any kind of Legal or Clerical qualification should be allowed to exercise every function, or to hold any office in the Law or Church, respectively, your Petitioners are persuaded that such a proposition would not be entertained by your Honourable House. And they know of no reason why an

enactment so levelling, so discouraging, and therefore so detrimental to the interests of science and learning, should be forcibly imposed upon the Medical Profession.

Your Petitioners, being convinced that none of these Bills will prove conducive to the best interests of the Medical Profession or of the Public, humbly pray that no one of them may be suffered to become Law.

They would earnestly implore the Legislature to amend the Laws relating to the Medical Profession, which grievously need amendment, by measures different from those now proposed, and by a Bill better calculated to promote the good of the Profession and the public, than any one of the Medical Bills now before your Honourable House.

And your petitioners will ever pray, &c.

### HOW TO COMMEMORATE THE ROYAL VISIT TO WARWICKSHIRE.

We have been requested to publish the following correspondence, the object of which will commend itself to every benevolent mind:—

*"To the Right Honourable Lord Leigh, Lord Lieutenant of Warwickshire."*

"Southam, 15th May, 1858.

"MY LORD,—The visit of her Majesty to Warwickshire will offer an opportunity to the loyal inhabitants of Warwick and adjacent places, to express the respect and honour they entertain towards their Sovereign. Many modes of doing this have already been suggested, the greater part of which, however, are, in my opinion, neither worthy of, nor fitted for, the occasion. I therefore respectfully suggest that, instead of making an occasion for feasting and giving of presents, it be celebrated by the establishment of that which will yield a permanent good—by kindness and help to the distressed, instead of individual self-indulgence.

"Thirteen years ago, when her Majesty passed through Northampton, the inhabitants commemorated the event by establishing a Royal Victoria Dispensary, upon principles differing in many most important respects from ordinary dispensaries. It was established and received its outfit by subscriptions from the wealthy, but for its Medical expenditure was dependent upon the contributions of those who were to be benefited by it. It was to be self-supporting. The contributors or free members were, by a fixed small weekly or monthly payment, to be entitled to medical attendance. It thus nurtured provident habits and self-denial. It preserved a healthy independence of spirit. It saved them from the palsying touch and the morally corroding influence of the beggar's alms.

"From the report for the year 1857, I find that this Institution has been most successful. The free members, consisting chiefly of artisans and their families, raised in that year the sum of £704 2s. 8d.; and their three Medical officers received the respective sums of £123 18s. 2d., £192 8s. 6d., and £262 9s. 7d., without the trouble of making out a bill.

"The persons who have subscribed this amount are of a class, that if this Dispensary had not been established, must, in illness, have been beggars of tickets for charity Hospitals, implorers of orders from parish officers, or deluded victims of quackery.

"I need not speak of the importance of good Medical care in preventing that waste of life which is, in fact, to that extent, an actual loss of the wealth of the country, but content myself with suggesting that her Majesty's visit be commemorated by establishing a similar Institution.

"I am sure that it will be far more gratifying to her Majesty to know that her visit has caused good to be done—especially to those of her subjects who most need it—than to be welcomed by any length of well-ordered procession or any magnificent gift to herself. Let her coming bring health and comfort to her poor subjects, and she will be pleased. The establishment of such an Institution would be in harmony with the well-known kindness and benevolence of our Queen, and would make her visit an event to be remembered, not merely during the passing day, but continually and with gratitude.

"The fund to be raised for the establishment of such an

Institution would be applied in furnishing it, paying rent, and for stationery, etc. It would, in all other respects, be supported by those who were benefited by it, and who would pay a very small fixed sum weekly or monthly. If there should be any surplus funds after establishing the Dispensary, they might be made the beginning of an auxiliary fund for helping the contributors to the Dispensary—and them alone—in unusual distress, by providing them with better dressed food, suitable delicacies, nursing, or visiting (for which purposes a committee of ladies would be very useful), so as to promote a speedy cure and the growth of health both in body and soul.

"Similar Institutions have been successful in several places.

"If this suggestion meet with approbation, I shall be glad to lay before your Lordship full particulars of the cost and mode of carrying it out.

"I have, my Lord, the honour to be,

"Your Lordship's humble servant,

"HENRY LILLEY SMITH."

"30, Portman-square, London, 17th May, 1858.

"Dear Mr. Smith,—I beg to acknowledge the receipt of your letter dated 15th inst. and quite approve of your proposals, which I consider admirable.

"Yours truly,

"LEIGH."

## PARLIAMENTARY INTELLIGENCE.

### HOUSE OF COMMONS.

#### PURIFICATION OF THE THAMES.

Mr. GRIFFITH asked the First Commissioner of Works whether the principle just put forth by Dr. Odling, the officer of health for Lambeth, that the perpetual agitation of the water of the Thames, and the flux and reflux of the tide, affected the oxidization of decomposing matters to that extent "that he has never been able to detect sulphuretted hydrogen in Thames water," might not be well worthy of further investigation, as offering possibly the means of escaping the hazardous and expensive drainage engineering undertakings that had been under consideration?

Lord J. MANNERS said that a select committee of that House had sat upon the subject, and any opinion he might give would therefore carry with it very little weight. If Dr. Odling was unable to discover sulphuretted hydrogen in the Thames water, he would recommend the hon. gentleman to inquire whether he was equally unable to discover it in the Thames air.

#### MEDICAL PRACTITIONERS BILL.

Mr. COWPER, in moving the second reading of this Bill, said he took it for granted that the necessity of legislation on this subject was universally admitted. If there was objection anywhere, it probably arose from those persons who were not members of the Medical Profession, but who wished to be supposed to belong to it—the class of uneducated ignorant quacks who practised on the credulity of the public, and who hoped, in the present disorganized, anomalous, and chaotic state of the Profession to pass for what they were not. (Hear, hear.) There were three objects which all the persons who had prepared Bills on this subject had kept in view. These were:—1. To raise to a uniform standard the education and consequent qualifications of all persons who entered the Medical Profession. 2. To have an authoritative register, clearly defining, and accessible to the most ordinary persons, those who have attained the prescribed qualification. 3. The removal of all those local jurisdictions which restricted a competent man from practising in any other part of the country than that in which the licensing body which passed him existed. (Hear.) To take any one of these three propositions separate from the others would be highly injurious to the Profession, and he might observe also that it would be disadvantageous to give to small licensing bodies a power of competing fully in that respect with larger and higher schools of instruction. (Hear, hear.) The council proposed by the Bill would be elected by the different examining bodies, so that if any injustice were complained of, a member of the body in

question would be present to defend its proceedings. If the council, representing, as it would, all the branches of the Medical Profession, including the Universities, should commit any injustice, an appeal against its decision would lie to the Privy Council. Some objection was made to the plan of registry proposed by his bill, and it was said that it did not distinguish between physicians and other members of the Medical Profession. It might be asserted with regard to physicians that nine-tenths of the number of patients were not under their treatment. He proposed to extend the power now possessed by the Universities or by the Apothecaries' Society to the persons registered according to the Bill. He did not think it possible by law to erect the Physician into a class separate and distinct from the rest of the Profession, because Physicians were a class not created by law. He did not, however, propose to touch the privileges of the Physicians as regarded their charter, so that they had no reason to complain. As to the objections of the College of Surgeons, he believed that their apprehensions of a diminution of their pecuniary resources, in the event of the passing of the Bill, were not well-founded. The Medical practitioners throughout the country, numbering about 14,000, and who were represented by the Medical Association, were favourable to his Bill. Upwards of 100 petitions from Medical practitioners had been presented in favour of his Bill, and at the end of last week there had been only one petition against it. He had reason to maintain, therefore, that the great bulk of the Profession wished to see his Bill pass into a law, and he believed that its provisions would be beneficial to the community. (Hear.)

Mr. BLACK said that the House had seen five Medical Bills in three years. So far from any legislation being wanted, he believed that the best Medical Bill would be one to repeal all previous legislation on this subject. He would move that the three Bills be all thrown out together. (A laugh.)

Mr. WALPOLE was inclined to think that the House had failed to adopt any Bill upon this subject because so many vague propositions had been brought forward, and no definite plan in reference to the evils complained of, or the remedies to be applied, had been suggested in a simple form, which would meet with general concurrence. The Bill of the hon. and learned member for Newcastle, the Bill of the noble lord the member for Haddingtonshire, the Bill of the right hon. gentleman now under discussion, and the Bill of the hon. member for Finsbury, all contained principles worthy of adoption; yet in each there were some points to which the House ought not to assent. (Hear, hear.) The difficulties in the way of dealing with the subject sprang from its being founded upon circumstances and laws which were totally incompatible with the age in which we lived, from its involving in consequence many anomalies and absurdities in reference to the privileges conferred either on Medical bodies or bodies which had the power of conferring medical degrees, which could not be exercised, or, if exercised, would not be advantageous to the community, and from their having to deal with interests of a most conflicting character in the endeavour to get rid of those anomalies and absurdities. Even when the right hon. baronet the member for Carlisle was a member of one of the most powerful Governments which had been seen for years, he found it impossible to frame a measure satisfactory to all parties, and although a select committee had been brought to a sort of compromise in order to settle the question, no sooner did they recommence the discussion in the House than they branched off in different directions and took different sides upon matters whereon they were unanimously agreed in the committee upstairs. He need not, therefore, apologize for stating that he could make no suggestion for the settlement of the question. (Hear, hear.) Upon the whole he had come to the conclusion that the best thing to do was to point out as clearly as he could the different evils of which the community had a right to complain, the different modes in which they were to be got rid of, and in reference to the three Bills, how far the evils might be got rid of, and how far remedies might be applied. The first great evil was that they had begun upon the wrong basis. From the middle ages, the Medical profession had got into the hands of the ecclesiastical authorities, who were unwilling to undertake the Surgical part of it, and hence the separation of the two branches. From that time to the present, by means of the statute of Henry VIII., the anomaly had existed of different licences or degrees in different parts

of the kingdom. There was a Medical body with powers to exercise exclusive authority within seven miles of London; and the Universities inherited from the ecclesiastical authorities the power of conferring degrees, giving a privilege to practise over other parts of England. In Scotland, the Colleges of St. Andrew's, Aberdeen, and Glasgow had the power of conferring degrees extending over the whole of the country, and not excepting the area of the capital; because the College of Physicians in Edinburgh had not that exclusive authority which was possessed by the College of Physicians in London. He might show that the rivalry between those Colleges in conferring degrees led to nominal, or worse than nominal, examinations. (Hear.) Another point of difference between Scotland and England was, that while in England Surgeons were distinct from Apothecaries, in Scotland they were combined. In Ireland, the Dublin University had the same privilege of conferring degrees as the Universities of Oxford and Cambridge; and, added to that, Parliament had given to the Colleges of Cork, Galway, and Belfast, affiliated to the Queen's University, "the same privileges as those conferred on the Universities of England," without defining or describing the extent of those privileges; so that at this moment they did not know whether the Queen's University in Ireland had power to extend permission to practise in other parts of England. The inference which he wished to have drawn was, that instead of continuing that anomalous state of things, instead of preserving exclusive privileges in one part of the kingdom, and instead of depriving the public of the right of calling in the advice which they believed to be the best, they should establish the principle of reciprocity of practice in all parts of the United Kingdom. (Hear, hear.) That was the first great principle. The second point was to form a register, which should not merely be a register of names, but should indicate whether the qualifications possessed by the persons in the register were such as entitled them to hold themselves out as practitioners. The third point was to constitute a council, which should be a supervising and controlling authority, and then the question arose how the council should be constituted. His opinion was, that the proposal of the right hon. gentleman (Mr. Cowper) was the best—viz. to make the council consist partly of representatives from the different medical corporations, and partly of nominees by the Crown, so as to give confidence to the public as well as to the Profession. He believed that they would do well to confine Medical Reform to those three points,—reciprocity, a register, and a council. As to reciprocity, the Bill of the hon. member for Finsbury gave it complete. The hon. member for Haddingtonshire confounded and blended together instead of keeping distinct and independent the different medical corporations, and he thought that a change which would be detrimental, because fair rivalry and competition would still exist if the medical bodies were kept distinct. The right hon. gentleman whose Bill was under discussion simply provided that every person registered might practise medicine or surgery, or medicine and surgery. As to the register, the hon. member for Finsbury gave any person a right to register, whether he had gone through any examination or not, and the public could not know whether the person registered was a duly qualified practitioner. The hon. member for Haddingtonshire provided that the registration should take place after the examinations—one preliminary and one professional, but he thought the effect would be to establish a minimum standard of qualification. The right hon. gentleman the member for Hertford intended to keep the different examining bodies with distinct and independent powers, but inserted the words, "subject to the council," which would have the same effect of inducing a *minimum* standard of qualification, which he thought every one must deprecate. (Hear, hear.) As to the council, the hon. member for Finsbury proposed no council at all, but only a substitute for one, which was defective. The hon. member for Haddingtonshire proposed a council wholly nominated by the Queen. The right hon. member for Hertford proposed a mixed council of representatives and nominees. He had already expressed his preference for the last form of council, but he wished the right hon. gentleman would consider carefully the enormous powers which were to be given to the council, and the want of provisions for keeping alive the distinct and independent character of the different Medical bodies. (Hear, hear.) By legislating soundly on these three particulars—recipro-

city of practice, a register of duly qualified practitioners, and the establishment of an authority partly constituted on the representative principle and partly on the principle of appointing persons who would be permanently resident here,—more would be done to reconcile conflicting interests than by taking any one of the bills separately. That course would be satisfactory generally to the Profession and to the public at large, it would be safe and prudent, and it would remove all serious impediments to legislating this Session. He would recommend, therefore, that the Bills of the hon. member for Finsbury and the noble Lord the member for Haddingtonshire should be withdrawn, and that all sides should unite in endeavouring so to amend the Bill of the right hon. member for Hertford as to make it satisfactory to all parties. He should be most happy to give every assistance in his power to the attainment of this object. (Hear, hear.)

Mr. HEADLAM said he had no fault to find with the principles laid down by the right hon. gentleman; but the best course would be, instead of leaving it to private members, himself to introduce the amendments which he thought necessary to carry them into effect.

Mr. WALPOLE.—I should have no objection to do that. (Hear, hear.)

Mr. HEADLAM.—If the right hon. gentleman would do that, the chances of legislating satisfactorily this year would be much increased. The Medical Profession had great reason to complain of former Governments in this matter, for they had not only refused to bring in Bills of their own to remedy the anomalies which they had admitted, but they had interfered with the progress of Bills brought in by private members. There was considerable unanimity of opinion in the Medical Profession as to the reciprocity of practice, and the expediency of establishing as good an education as could be obtained, with an examination which would be at the same time a satisfactory test of proficiency without being so high as to discourage persons from entering the Profession, and so increasing the number of unlicensed practitioners. If legislation were confined to those points, there need be no difficulty in passing a useful Bill this session. His objection to these three Bills was, that they were based on the theories of individual members, which had no chance of being passed into law or of being accepted by the Profession. Though the Bill which he had himself introduced last year had been defeated by the opposition of the right hon. gentleman the member for Hertford, he should not retaliate upon him on the present occasion, but, on the contrary, would give every assistance in his power towards introducing such amendments in this Bill as would make it satisfactory to the Profession and the public at large.

Mr. T. DUNCOMBE thought the Home Secretary had very fairly dealt with the objections to these three Bills, and the best course which could now be taken would be for the Government to introduce a Bill of their own instead of merely bringing forward amendments in the measure of the right hon. member for Hertford. He himself should be very glad to withdraw his own Bill, so as to leave the field open to them. The system of register which he had proposed to establish was an important step in Medical Reform; but the question of Medical education was attended with so many difficulties that he scarcely thought the House could be induced to come to any agreement on it. The question of the granting of diplomas, which was to a great extent a matter of fees, was equally difficult. He had seen so much of the jealousies and bickerings of the Profession, that he was not surprised at the unwillingness of the Government to touch the subject. A register such as that proposed by his Bill was the chief thing needed; and as for the Medical Reform in general, there could not be a worse tribunal than the House of Commons to judge and decide on it. If they stuck to political reforms and clerical reforms there would be work enough, but he would advise them to have nothing to do with the doctors. (Laughter.)

Lord ELCHO said the register of the hon. gentleman's Bill would give no security that persons placed on it were thoroughly qualified for the Profession. It would perpetuate the evils of the present system, and would, in fact, simply be an official Medical Directory. With regard to the Bill which had been introduced last year by the hon. and learned member for Newcastle, the manner in which it proposed to carry out his principles was most objectionable. It benefited the corporations by doing gross injustice to the

universities. One of the chief things to be guarded against was the rendering too stringent the powers of these corporations; and he warned the House against the efforts which those bodies would be certain to make to carry out their aim when the Bill got into committee. After referring to the leading provisions of the several measures before the House the noble lord said that his object in introducing a Bill with respect to the Medical Profession had not been that he might attach his name to a measure of Medical Reform, but that he might prevent another proposition from becoming law which he believed would have been most unjust in its operation. Recognising in the Bill of the right hon. member for Hertford the principle of sound Medical Reform, and believing that it would have a better chance of passing than his own Bill, he should withdraw the measure which stood in his name, and should be happy to render all the assistance in his power in perfecting the Bill of the right hon. gentleman. In the event of no Bill being passed this year he suggested to the Secretary of State for the Home Department that he should issue a Royal Commission to inquire into the subject.

Mr. LEFROY and Mr. Grogan expressed their approbation of the Bill of the right hon. member for Hertford, and their gratification that there appeared to be at length some probability of passing a comprehensive and satisfactory measure upon this long-vexed question.

Mr. Cowper briefly replied.

After a few words from Mr. Craufurd and Mr. Hadfield, The Bill was ordered to be committed.

Mr. Duncombe postponed till the 23rd inst. the motion for the second reading of his Medical Profession and Medical Corporation Bill; and,

On the motion of Lord Elcho, the order for the second reading of his Medical Profession Bill was discharged.

#### THE VACCINATION ACT.

Mr. MonseU asked the Vice-President of the Privy Council Committee, whether his attention had been called to the fact, that out of 1636 deaths reported to have taken place from all causes in the quarter ending the 31st March, 1858, at Burton-on-Trent, Sheffield, and Merthyr Tydvil, 419 were reported to have been caused by small-pox; and whether he proposed to introduce any amendment of the Vaccination Act?

Mr. Adderley said it was unfortunately too true that this great mortality through small-pox had occurred. From all the information he had been able to collect on the subject, he believed that the prevalence of small-pox was owing as much to bad vaccination as to neglect of vaccination. Indeed, the state of vaccination throughout the kingdom was sufficient to create alarm. It had engaged his attention, and he had given much consideration to the question in what manner it was desirable to amend the act. There were two ways of doing this—either by making the penalties for neglect more stringent, or by making better provision for ensuring good vaccination. He was not prepared to make the penalties more stringent, but the second clause of his Public Health Bill would confer additional powers on the Privy Council in respect of giving notice of the parties who were contracted with.

In reply to Mr. Paley,

Mr. Adderley said that the second reading of the Public Health Bill would come on that evening. Though it was proposed that the Board of Health should expire in September, it was not intended that that should interfere with the Medical officer. With regard to whether the Local Government Bill, which stood for committee on Thursday, would affect the staff of the Board of Health, if that bill passed, the general Board itself would expire, and the staff would expire with it.

The Public Health Bill was read a second time on Monday evening last.

**THE SMOKE NUISANCE.**—Mr. Ayrton obtained leave to bring in a bill for the purpose of abating the smoke nuisance in the metropolis, by compelling furnaces to be so constructed as to consume their own smoke.

**PETITIONS.**—For the Redress of Grievances of Medical Officers of Poor Law Unions.—By the Attorney-General, from Medical officers of the Woodbridge Union. In favour of Mr. Cowper's Medical Bill.—By Mr. J. C. Ewart, from members of the Lancashire and Cheshire branch of the Medical Association.

## REPORTS OF SOCIETIES.

### MEDICAL SOCIETY OF LONDON.

MAY 22, 1858.

Dr. MERRIMAN in the Chair.

Mr. WEEDEN COOKE read a paper on

#### THE ARREST OF CANCER.

After an exordium deprecatory of Medical scepticism which led to fatalism, and in praise of a just confidence in man's powers to heal his fellow man, "which," said the author, "is only bounded by his intellect, by his inability always to control the object of his treatment, and by time which wears out the machine he works upon," Mr. Cooke referred to the different forms of cancer, scirrhus, epithelioma, medullary sarcoma, cystic sarcoma, etc., as having broad outlines too distinct to the eye and the touch to require often the delicate but sometimes illusive aid of the microscope. He then spoke of the recurrence of cancer after operation as so peculiarly characteristic of this disease that he was disposed to include in the same category all recurrent so-called benign tumours. After noting the peculiarities of the different forms of cancer, the author continues:—"In contemplating the phases of this disease a glimmer of cheerfulness is shed over the sombre picture by a knowledge of the fact that scirrhus, the least active, is also the most common form. 1858 cases treated at the Cancer Hospital yield of scirrhus 1344, epithelial 389, medullary 77, and cystic 35; so that scirrhus is as nearly three to one of all the other forms, and it is in this large majority that remedies are of most avail. The mamma is its most wonted seat, almost four-fifths of the scirrhus cases occupying that gland." The period of life at which the disease appears corresponds to the cessation of the catamenia—the average age of attack being 44. The blood at this period is rendered impure by the absence of that customary process which in so marked a degree clarifies the system when it is in force. How the scirrhus is formed out of deteriorated blood may be imagined, but cannot be known. Even hereditary taint yields little towards the solution, since but one in seven can trace any predisposition. The fact, however, of the climacteric association is still further shown in the Registrar's report for the last quarter, by which it appears that after forty years and upwards the deaths from cancer form four-fifths of the whole number. On the other hand the influence of local injury is only testified to in one in eight cases. The broad fact, therefore, stands out that in the very large majority of scirrhus cases they do develop themselves at that climacteric period when the vigour of life receives a severe shock, the effects of which it is the peculiar province of Medical science to soften and subdue. For many years now it has been the custom to cut out this local manifestation of a general disease, and very recently to destroy the tumour by a cauterising process which has the peculiar advantage of prolonging the operation some forty or fifty days. Before the present century, operations for cancer were not so ripe, many eminent surgeons having opposed them when they were performed either by means of the knife or caustic, which latter was at that time enjoying an ephemeral reputation in France. Specifics then became fashionable; arsenic and hemlock enjoyed the highest reputation, but these proving unsatisfactory, early extirpation was again proposed, and has been most freely practised, encouraged, no doubt, by the introduction of anæsthesia, by ether and chloroform. That this proceeding is a cutting of the Gordian knot, and not a skilful unravelment, cannot but be acknowledged, when we find that of 207 cases of operation observed at the Cancer Hospital, the disease has returned (taking the average) in fifteen months. A recurrence of the disease is more uncontrollable than the original tumour. A dyscrasia of the system is produced by the operation, and so greater activity of disease is provoked. By removing the tumour the reservoir is taken away, and the cancer cells are distributed over the whole economy. "Experience," says Mr. Cooke, "leads me to the conclusion that there is in a great number of these tumours a natural ebb tide. The tumour

grows at first rapidly, after a time, slowly; it then remains stationary, and at last begins to waste, until gradually it almost disappears. These favourable cases are seen in persons of cheerful temperament. In other persons the progress will be the same, but the termination a spontaneous sloughing out of the whole tumour. Sometimes the wound remaining will fill up and heal, or it will remain a dry scab for years without inconvenience, or a small superficial ulcer will continue to give some inconvenience, which may be relieved and kept in subjection for years by judicious treatment." Taking the climacteric disturbance as the grand exciting cause of the development of cancer, it is only rational to expect when that disturbance subsides, provided the patient is well supported and well managed, the mind relieved of all fear, and the cancer itself neither tattooed with caustics nor excised, that the cause being removed, the effect will have no further serious existence; that, in fact, the active cancerous tumour will become a mere inert fibrous mass, which is in a great measure reabsorbed by the neighbouring vessels. Numerous cases were read by the author, illustrative of his views, and showing the advantage of constitutional tonic treatment. He then dwelt upon the importance of the inculcation of hope, "that charm for every woe," by both Surgeon and friends; "it medicines the body no less than the mind, and should be administered with a full conviction that it is a most valuable therapeutic agent, and not as an amiable delusion." He spoke also of the influence of temperament, and suggested the simple division of "cheering" and "desponding," instead of the old and more complicated arrangement of Hippocrates. It will invariably be found, that while a melancholy mind in which hope cannot be raised, is the severest enemy with which the Surgeon has to battle, a cheerful temperament is such an aid to art, that with it a sufferer from cancer will tide over the evil days, and live to the usual period of man's existence. The treatment most relied on was good nourishing diet with beer or wine. Soda to correct the secretions if necessary. Bark and hydrochloric acid, or iron as a tonic. Iodine and mercury are positively injurious, and opium should never be resorted to, whilst there is any hope of restoring the patient. As a local application, lead, either as a supporting plaster, or as a lotion, when there is much activity in the tumour, has a very sedative effect. The carrot poultice cleanses an ulcerated surface admirably, if frequently renewed, while the chlorate of potash lotion is the most effective in healing the open wound. These and other simple methods of dealing with the disease, which are all founded on the principle of restoring and preserving, and giving support to the vital principle, wasting no time in looking after impossible specifics, will advantageously displace the use of the knife and caustic in the majority of cases, "although," said Mr. Cooke, "I am anxious to state that there are cases, *ex. gr.*, epithelial cancer of the lip and of the extremities, as well as some forms of medullary cancer; in which operation is desirable and beneficial." A letter from Mr. Cooper, Consulting Surgeon to the Liverpool Infirmary, was quoted, in which he says:—"For my own part I confess that I have known few cases—scarce any—where the diagnosis has been unquestionable—in which extirpation has been successful. On the other hand I have seen many cases, not interfered with by the knife, whose lives appeared little, if at all, shortened by the affection." In conclusion, the author affirmed modestly but decidedly that constitutional treatment was proved in its results to be immeasurably superior to operative treatment, so much so, that whereas the disease always returns after operation, and then with an increased impetus; by constitutional measures, which should include moral as well as physical support, and soothing local applications, it is arrested in its destructive progress, the new blood throws off the vicious habit of the old, no more cancer cells are laid down. The old disease becomes a mere inert foreign body, which sloughs and is thrown off from the renovated system, or is gradually carried off with the other effete matters of the body. The plague is stayed, and the remainder of life may continue so uninfluenced by the terrible conflict which has been won, that length of days may be attained, and life ultimately ebb out in the calm twilight of evening.

Mr. BARWELL suggested questions respecting the proportion of cases relieved, whether it was possible to trace them to the end, and whether they eventually died of cancer or of other diseases.

Mr. HARRISON did not see how cessation of the menses could be set down as the cause of cancer, seeing that men had cancer as well as women, although in a less degree. He approved the constitutional treatment, and especially the moral management suggested.

Mr. DE MERIC thought that credit was due to the author for resisting the always tempting and easy solution of the difficulty by operating. He related the unfavourable results of operation in his own hands, the disease returning very quickly after extirpation; and argued that as patients live longer without operation, it was desirable to adopt the constitutional method of treatment.

Mr. HUNT would have been glad to have heard more respecting the diagnosis of the disease. He had no doubt that this was perfectly easy and familiar to the author, but there were sometimes cases which were very difficult to decide upon. He related a case of ulcer at the angle of the mouth, which had been removed by operation and returned. It was afterwards seen by Dr. Fell, under whose treatment the ulceration increased. Microscopic examination of the secretion showed the presence of a large quantity of fat cells, which, in his opinion, indicated lupus. Mr. Hunt also related a case of cancer of the lip, which returned and killed the patient very soon after an operation; and another case which got well by constitutional treatment. He was therefore of opinion that operations were undesirable.

Mr. CANTON believed in the spontaneous degeneration of cancer, and illustrated it by a case of scirrhus of several years' standing in the breast, with enlargement of the axillary glands. He removed the whole of the disease, and found the cancer cells shrunk and faded, which led him to believe that these tumours after a time become benign. He was disposed to think that the greater prevalence of cancer in unmarried than in married females, and its infrequency in males, suggested some connexion with celibacy. He related cases showing the rapid return of cancer after operation, and the injurious influence of the mental depression which attended operations. Great mental distress was often apparently the cause of the development of cancer. He had not seen any benefit from treatment in cancer of the uterus. There was a great difficulty in tracing cases to their termination; it would be very desirable to establish a general register, so that cases passing from one Hospital to another might, by an interchange of reports, be made complete, by bringing the history and treatment into one focus.

Dr. ROGERS doubted the connexion of cancer and the cessation of the catamenia. He had seen pressure and ice used without any benefit, and related the cases of two sisters, one of whom was operated on and died soon, the other had no treatment, and lives in tolerable comfort.

Dr. ROURN considered it remarkable that, as Mr. Cooke formerly advocated operation, now he is opposed to it. He placed confidence in arsenic as a remedy, and had lately employed galvanism, with benefit in one case, and in others without any good effect.

Mr. W. COOKE, in reply, was gratified at the reception his observations had met with. The discussion had strengthened his views as to the desirableness of abstaining from operation. He certainly had begun by following the instructions he had received in the schools, but had been forced by experience to change his opinion, and adopt the constitutional treatment without operation in the majority of cases. In reply to the objection, that, as men have cancer, the cessation of the catamenia could have nothing to do with it, Mr. Cooke reminded the society that Sir H. Hallford and Dr. Roget had written of a climacteric dyscrasia in men, the presence of which would go rather in support of, than be detrimental to, his argument. He had not contemplated entering into the subject of diagnosis, owing to the limited time allotted to the paper, but would in a word give "induration" as the necessary accompaniment of a cancerous ulcer. The case mentioned by Mr. Canton, of degeneration of the cancer-cells, was strongly corroborative of the views put forth in the paper. Statistics would not, he thought, support the opinion, that cancer was more prevalent in unmarried than in married persons. Pressure and ice had not been of any service, but rather injurious, while galvanism required more evidence in its favour to be spoken of one way or the other.

The Society then adjourned.

## UNIVERSITY OF ST. ANDREW'S.

By an unintentional error on the part of the printer, the list of candidates for honours at the University of St. Andrew's was not given last week in their due order of precedence. The list should have stood as follows:—

## Class I.

RULE, SAMUEL, London Hospital.  
COOK, HENRY, H.E.I.C.S.  
BOWEN, ESSEX, late Royal Artillery.  
POTTER, HENRY, Limerick.

## Class II.—None.

## MEDICAL NEWS.

**ROYAL COLLEGE OF SURGEONS.**—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at the meeting of the Court of Examiners on the 28th ult.:—

CRESSWELL, A., Frederick-place, Gray's Inn-road.  
CRUIKSHANK, J., Fochabers, N.B.  
EWEN, A. B., Long Sutton, Lincolnshire.  
JEFFERSON, J. B., Islington.  
LOCKWOOD, J., Kirkeaton.  
McCABE, F. X. F., Hastings.  
PEARSE, A., Norwich.  
SAMS, I. J., Blackheath.  
SOMER, J., St. Cleather, Cornwall.  
TOMLINSON, E. D., Wakefield.  
WATSON, J., Loughborough.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, May 27, 1858:—

ARNISON, WILLIAM C., Allendale, Northumberland.  
CLAPTON, WILLIAM, Stamford, Lincolnshire.  
GRABHAM, GEORGE WALLINGTON.  
PALFREY, JAMES, Broad-street, Deal.  
STEPHENSON, JOHN, Leeds.  
TEIMNELL, THOMAS JAMES, Castletown.

## DEATHS.

**BULL.**—May 31, at Brighton, Thomas Bull, M.D., aged 52, formerly of Finsbury-square.

**JAMIESON.**—May 31, at Peterhead, Patrick Jameison, in the 64th year of his age, forty-four years a Practitioner in Peterhead.

**MITCHELL.**—Professor John R. Mitchell died after a short illness, at Philadelphia, on the 4th of April, in the 65th year of his age. Of Scotch descent, and commencing his education at Edinburgh during its zenith of Medical fame, on his return to the United States he soon attained high Professional eminence. Appointed in 1841 as Professor of Medicine in the Jefferson Medical College, he was chiefly instrumental in raising that Institution from its drooping condition to its present flourishing state. At one time he was said to lecture to the largest class in the world. He was a frequent contributor to the Medical journals, and among his papers those on the "Penetration of Gases," and on the "Cryptogamous origin of malarial fevers," excited especial notice.

**MOGRIDGE.**—May 24, at Sidmouth, Theodore Hands Mogridge, L.R.C.P. Lond.; M.R.C.S. Lond. 1834, aged 47.

**ROWLAND.**—At Swansea, Wm. Rowland, M.D. St. And., 1844; M.R.C.S. Eng. 1833; F.R.C.S. (Hon.) 1844; L.S.A. 1824; aged 56.

**WARD.**—May 26, at Leeds, James Ward, L.S.A. 1826; M.R.C.S. Eng. 1827; aged 54.

**WIDMER.**—May 3, at Toronto, the Hon. Christopher Widmer, M.D., aged 78.

## APPOINTMENT.

On Tuesday, May 25, Mr. Joseph J. Pope was elected, by a majority of 11 to 5, to the post of District Medical Officer of the borough of Liverpool. Mr. Pope has held the position of Senior House Surgeon to the Liverpool Southern Hospital for the past twelve months.

**ROYAL COLLEGE OF SURGEONS.**—A meeting of the Fellows of this College will be held at the College on the 1st of July, at 1 o'clock precisely, for the election of three Fellows into the Council of the College, in the room of two Members going out in rotation, and the late Mr. Travers.

**ROYAL MEDICAL AND CHIRURGICAL SOCIETY.**—The following gentlemen will be balloted for as Fellows on Tuesday evening, June 8th, 1858. The ballot will be opened at half-past 7 o'clock, and will close at half-past 8 precisely:—Benjamin Godfrey, William Mackay Ogilvie, John William Ogle, and George Scratchley.

**ELECTION OF PROFESSOR SEDGWICK AT THE ACADEMIE DES SCIENCES.**—The Committee appointed to make out a list of candidates for the post of Corresponding Member in the section of Mineralogy and Geology, sent in the name of Professor Sedgwick of Cambridge on the first line, Sir Charles Lyell on the second, and on the third, a long list of continental and American geologists. The Academy elected Professor Sedgwick by 38 out of 46 votes present.

**THE BLACKBURN INFIRMARY.**—The foundation stone of the infirmary was laid on Monday, by W. Pilkington, Esq., the mayor, assisted by Stephen Blair, Esq. There was a large number of persons present. The inscription on the plate which was to cover the cavity in the stone stated that the mayor, the originator of the building, had given £2000 towards its erection, and £100 per annum towards its future support; that the site was a second donation of Joseph Fielden, Esq., the lord of the manor; that a bazaar had realized £2,839, and the remainder contributed by voluntary donations from amongst all classes.

**QUACKERY AND SUICIDE.**—(*From a Correspondent.*)—A case of suicide, the result of Quackery, occurred at Warrington a few days ago. A young man of the name of Ashton, by trade a coachmaker, had contracted syphilis, and had consulted a herbalist. Finding himself getting worse, and almost unable to follow his employment, he applied to a regular practitioner. This gentleman found the prepuce phymosed and gangrened, the penis at the same time being greatly swollen. The poor man on hearing how matters stood, and that he would lose part of the penis by the mortification which was evidently spreading, seems to have become phrenzied; he went home, went directly to bed, and cut his throat with a razor. His wife hearing a gurgling noise, went up-stairs, and made the fearful discovery. Dr. Martin and Mr. Steel were in attendance in a few minutes, but so determined had been the deed, that the man was quite dead. Besides his wife he leaves two young children. An inquest was held on the body, and a verdict of temporary insanity returned.

**HOSPITAL FOR CONSUMPTION, BROMPTON.**—On Thursday last the annual meeting of the governors of this institution was held at the Hospital, Brompton, the Earl of Manvers presiding, supported by the Hon. A. Kinnaird, M.P., Mr. J. Ivatt Briscoe, M.P., Sir John Forbes, Sir H. Foulis, Sir P. Pole, the Hon. R. S. Pierrepont, General Fanshawe, Major Munn, Drs. Tooke, Smith, Shaw, Quain, and Cotton, Mr. John Labouchere, etc. Mr. Rose, the hon. secretary, read the 17th annual report, which expressed the regret of the committee, that, in consequence of the financial position of the charity, there had been a diminution in the number of in-patients received in the Hospital. The funds had not been sufficient to keep the whole Hospital open, and this circumstance, together with the debts of the charity, had caused the committee to close a portion of the building, and now one entire wing of the Hospital, containing 80 beds, was shut up. By the reduction in the expenditure the state of the funds had been bettered, but still increased exertions were required to free the Hospital from debt, to extend its usefulness, and to enable the whole of the 85 beds vacant to be filled by the clamorous applicants for admission. Mr. Briscoe, M.P., moved, and Sir John Forbes seconded the following resolution:—"That the governors in annual court assembled, finding that Mr. Cross, through the infirmity of deafness, has been compelled to resign the office of secretary, cannot part from him without expressing their sincere regret at this enforced termination of his long and useful connexion in that capacity with the Hospital, the duties of which he has discharged in a manner and spirit alike honourable to himself, satisfactory to the governors, and beneficial to the charity." This was carried unanimously, and also thanks to the chairman.

## VITAL STATISTICS OF LONDON.

Week ending Saturday, May 29, 1858.

## BIRTHS.

Births of Boys, 904; Girls, 788; Total, 1692.

## TO CORRESPONDENTS.

*Mr. Thomson.*—We received notice of the hearing of the case at the Bloomsbury County Court, but having been unable to attend, we shall be happy to receive a short report of the proceedings, if they should possess any point of interest to the Profession.

*Mr. Samuel Rhind.*—1. A Visiting Medical Officer is always appointed to a private Asylum or Retreat, unless the proprietor is himself a Medical man. 2. The appointment is made by the Proprietor, and confirmed, or otherwise, by the Lunacy Commissioners. 3. Only private interest.

*Desipiens.*—The Archbishop of Canterbury does possess the power, by law, to grant the degree of Doctor of Medicine. This very absurd power must have been granted at a time when most of the offices of responsibility and patronage were vested in the Church, without any reference to education or qualifications.

*A Student.*—The successful candidates for the appointment of Assistant Surgeon in the East India Company's Service must depart for India within three months, or their appointment becomes void. The price of an outfit is about £100.

*Philo-Botanicus.*—There are very good opportunities for the study of Medical Botany at Kew Gardens, and also at the gardens in the Regent's Park. To obtain admittance to the latter, a member's order is necessary.

*Inquirer.*—The Society of Apothecaries have no charter in respect to the examination of Candidates for Medical Licences. They exercise the powers given to them in 1815 by virtue of an Act of Parliament. Their powers would probably be modified under any Medical Reform Bill.

*Mr. H. H. Watson* is thanked for the newspaper containing the additional correspondence on the question of whether sulphuric acid, as first obtained in the manufacturing process, is oil of vitriol. We think Mr. Watson is entitled to great credit for the zeal and ability which he has shown in the proceedings; but still we cannot blame unlearned persons of the laity, for taking a mere common-sense view of the case.

**ERRATUM.**—In our last No., p. 566, 2nd col., instead of "Mr. West, published in the last number of the *Midland Counties Journal*," it should read, "Dr. Wade in the last No. of the *Midland Quarterly Journal*."

## TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Allow me to mention (as a Cambridge Lic. Med.) that your answer to B. A. Cantab. is hardly correct. A Bachelor of Medicine is allowed by courtesy to be called Doctor everywhere except in his own University; as a Licentiate must be either a M.B. of one year's standing or a M.A. of four years' standing, and as he must have passed the whole examination required for the degree of M.D., he must, *a fortiori*, be entitled to be called Doctor.  
I am, &c., M.D.

## TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—About three months since, when reading one of your journals, my attention was directed to an article bringing before the notice of the Profession a preparation which the author had found possessed of valuable antiseptic properties.

Having a case under my care in which such an agent would prove, to say the least of it, very agreeable, I have searched repeatedly the numbers for this year, but hitherto fruitlessly, in order to discover its composition. My object in writing is to see if you, or any of your readers, can help me

out of my dilemma, by informing me of the whereabouts of the missing article, for which information I shall feel greatly obliged. I regret that my memory has so far played the traitor that I am able to give but little clue as to my wants.

It appeared, I think, in March, and was of tolerable length. Manganese, in some form, played a part in the composition, and the preparation possessed this advantage over other agents of this class, that, whereas, they destroyed one effluvium, but created another almost as objectionable, it was equally efficacious without any inherent odour. I may remark that I do not refer to "Boutigny's Fumigating Powder," mentioned February 7.

I am, &amp;c.

INQUIRER.

## TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I wish to ask through the medium of the *Medical Times*, whether my brethren consider the following circular sent you for insertion is strict Professional, or do they think with me that it savours very much of what the quacks would say of themselves? I am, &c.

May 31st, 1858.

M.D., a Ten Years' Subscriber.

"THOMAS BLAKE, M.D.,

"Licentiate of Apothecaries' Hall, and Member of the Royal College of Surgeons, London; Licentiate of the College of Physicians and Surgeons, Canada East; and Member of the University Medical College of the City of New York, United States.

"Dr. Blake begs to announce to the inhabitants of Askern and the neighbourhood, that he has commenced the practice of his profession in the above place, and has taken the house lately occupied by Mr. Wikeley, Surgeon. Dr. B. trusts that his professional qualifications, together with his numerous testimonials from many eminent members of the profession, will furnish sufficient evidence of his ability to give satisfaction to those who may favour him with their confidence.

"Dr. B. would intimate, that his professional education has not been confined exclusively to this country, he having availed himself of the great facilities for study afforded by the principal Medical Schools in the United States of America, and in Canada.

"Askern, January 1, 1858."

## COMMUNICATIONS have been received from—

DR. SIMPSON, Edinburgh; Mr. REDFERN DAVIES; Mr. WILLIAM PARKIE; DR. HERBERT BARKER, Bedford; Dr. ANDREW SMITH; THE GENERAL BOARD OF HEALTH; Mr. WEEDEN COOKE; THE SOCIETY OF APOTHECARIES; Dr. ANGUS MACMILLAN, Hull; Mr. P. LE NEVE FOSTER; THE POOR LAW MEDICAL REFORM ASSOCIATION; Mr. RICHARD GRIFFIN; THE ROYAL INSTITUTION; THE ROYAL MEDICAL BENEVOLENT COLLEGE; Mr. HORSBY; York; Mr. J. J. FOX; Mr. R. H. COOKE; M.D., A TEN YEARS' SUBSCRIBER; Mr. TAPP; Dr. CHOLMELEY; Dr. WADE, Birmingham; Mr. HENRY SYMES; Mr. SAMUEL RHIND; Dr. J. CAMERON, Liverpool; Mr. THOMSON; THE ROYAL COLLEGE OF PHYSICIANS; INQUIRER; Dr. MARTIN DESPENS; Mr. POPE; A STUDENT; PHILO-BOTANICUS; INQUIRER.

## APPOINTMENTS FOR THE WEEK.

June 5, Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m.; Charing-Cross, 1 p.m.

ROYAL INSTITUTION, 3 p.m.: Edwin Lankester, M.D., F.R.S., F.L.S. "On the Vegetable Kingdom in its Relations to the Life of Man."

## 7. Monday.

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.; Orthopaedic Hospital, 2 p.m.

ROYAL INSTITUTION, 2 p.m.: General Monthly Meeting.  
EPIDEMIOLOGICAL SOCIETY, 8 p.m.: Mr. J. N. Radcliffe, "On the Distribution of the Mortality from Hydrophobia in England, as an Illustration of Certain Peculiarities in the Mode of Extension and Prevalence of Epidemic Diseases; with Suggestions for the better Observation of Epidemics."

## 8. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.  
ROYAL MEDICAL AND CHIRURGICAL SOCIETY: Ballot, 7½ p.m.; Meeting, 8½ p.m.; Dr. Garrod, "On Gout;" Dr. Piddock, "On Iodide of Calcium;" Dr. Renneke (of Western Australia), "On Excess of Diet as a Cause of Disease."

ZOOLOGICAL SOCIETY, 9 p.m.  
ROYAL INSTITUTION, 3 p.m.: J. P. Lacaita, Esq., "On the History of Italy during the Middle Ages."

## 9. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Orthopaedic Hospital, 2 p.m.  
GEOLOGICAL SOCIETY, 8 p.m.

## 10. Thursday.

Operations at St. George's, 1 p.m.; Middlesex, 12½ p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.  
ROYAL SOCIETY, 8½ p.m.

## 11. Friday.

Operations at the Moorfields Ophthalmic, 10 a.m.; Westminster Ophthalmic, 1½ p.m.; Great Northern, 2 p.m.  
ROYAL INSTITUTION, 8½ p.m.: Mr. Faraday, "On Mr. Wheatstone's New Electric Telegraph."

## EXPECTED OPERATIONS.

King's College Hospital.—The following operations will take place this day (Saturday), at 2 o'clock:

Talipes varus; hare-lip; false joint in femur. By Mr. Ferguson. Excision of head of femur. By Mr. Bowman.

## ORIGINAL LECTURES.

## LECTURES

ON

THE ANATOMY, INJURIES, AND DISEASES  
OF THE HEAD,

DELIVERED IN THE

Theatre of the Royal College of Surgeons of England.

By PRESCOTT HEWETT,

Professor of Anatomy and Surgery to the College.

## ON FRACTURES OF THE SKULL.

## LECTURE IV.

(Continued from p. 520.)

I consider myself fortunate in having been able to gather together some thirteen cases of recovery after a fractured base, in which the state of the broken bones was ascertained by dissection some time after the accident.

A man met with a severe injury of the head, which subsequently led to an affection of the brain, and he died three months after the accident. An extensive fracture, which had not been suspected, was then discovered at the base of the skull; this fracture beginning in front of the mastoid portion ran through the extremities of both petrous bones, and through the sella Turcica. The broken bones were about a line distant from each other. No attempt had been made at reparation.

In a case reported by Mauran, the patient survived an injury of the head three years, during which he suffered greatly. When the head was examined, a piece of the petrous bone was found broken off, and around this an abscess had formed.

In a case reported by Mr. John Davies, of Hertford, the patient committed suicide five months after a severe injury of the head, the symptoms of which had been those of a fractured base. In the left temporal bone were the remains of a fracture running obliquely upwards and outwards between the squamous and petrous portions, splitting the Eustachian canal, as far as the tympanum; and another line of fracture also extended from the tympanum to the groove of the lateral sinus. The line of fracture was so imperfectly united that the broken parts of the bone were separated from one another during the working of the saw.

In a case, which was under the care of Mr. Stanley, in St. Bartholomew's Hospital, in 1840, the patient, aged 9 years, died on the 86th day after a severe injury of the head, accompanied by bleeding from the ear. A line of fracture was traced from the squamo-parietal suture to the petrous portion, through the middle fossa of the skull. The bones were quite separated, and without the slightest traces of an attempt at union. The edges of the bones were bloody, and not in the least rounded off. And what makes this case still more interesting is that the clavicle, which had also been broken at the time of the accident, was firmly united by callus, ensheathing the broken extremities of the bones, and completely fixing them.

A healthy man, 40 years old, fell from a height of twelve metres on to his feet. The only immediate symptoms were those of slight concussion, which soon passed off. But the accident was subsequently followed by cerebral mischief, which led to the death of the patient four months afterwards. Latterly, the case was under the care of M. Robert at the hôpital Beaujon. At the examination of the head, the posterior clinoid processes were found broken off from each other, and from the lamina quadrata; the right petrous bone also presented in its upper third an extensive fracture running in a transverse direction; a large fragment was completely separated from the rest of this bone.

A man, aged 46, was admitted into the Glasgow Infirmary, for a severe injury of the head, with bleeding from the right ear, caused by a fall down stairs, which had happened six days before. Ultimately this patient so far recovered as to be dismissed from the Infirmary at the end of eight weeks. Nine days afterwards he was seized with cholera, and died on the

5th day, under the care of Dr. Laurie. He had thus lived close upon eleven weeks from the time of the accident. On removing the dura mater, and carefully examining the bone, a fracture was found to extend from the superior part of the right parietal bone along its posterior margin, and a few lines from the lambdoid suture, joining the suture between the occipital and temporal bones, and terminating at the jugular fossa. On the interior of the right half of the occipital, and a portion of the corresponding parietal bone, there was a considerable deposit of ossific matter which had nearly obliterated the groove of the lateral sinus. Between the fractured surfaces of the bones, there were a few particles of ossific matter deposited, but the junction was far from being completed.

M. Richet states that he had under his care a man who had met with an injury of the head, which was followed by a serous discharge from the ear. Recovery took place, for a time at least. But five months afterwards, and without any premonitory symptoms, strabismus made its appearance; this was followed by cerebral symptoms, and the patient died. At the post-mortem examination a fracture was discovered in the malar bone, from whence it was traced into the base of the skull, cutting across the petrous bone, and terminating in the foramen magnum. At first no trace of the fracture could be discovered in the petrous bone, notwithstanding the most careful examination; and it was not until after this bone had been macerated in nitric acid for a month, that the course of the fracture was clearly made out.

The only preparations which I can refer you to in our London museums are six in number, and three of these, it so happens, are in the Museum of St. George's Hospital.

In the first of these preparations (a) the line of fracture, starting from the outer part of the right frontal eminence, passes downwards, behind the external angular process, into the great wing of the sphenoid, and obliquely across the back part of the orbital plate of the frontal, then through the lesser wing of the sphenoid into the body of this bone, where it terminates at the inner part of the left optic foramen. This extensive line of fracture is, in some parts, completely filled up by new bone inlaid between the edges, and in other parts there was merely a dense layer of fibrous tissue lying between the broken bones. The most perfect union is in the perpendicular portion of the frontal, and especially in the lesser wing of the sphenoid, where the fracture is scarcely perceptible. The inner surface of the bones presents, in some parts, an extensive deposit of new, spongy bone, extending, in several places, far beyond the line of injury. The patient, a middle-aged man, lived two months after a very severe injury of the head, from the effects of which he had, however, all but recovered, when he was attacked with erysipelas of the scalp, and died.

The second preparation (b) was taken from a man, aged 45, who died of malignant disease of the stomach and liver. Some nine weeks before his death this man had met with a severe injury on the left side of the head, accompanied by bleeding from the left ear, and from the nose. The preparation shows a fissure, from three to four inches long, passing from the central part of the left parietal obliquely through the squamous portion of the temporal, where it divides into two branches, one running onwards, as Mr. Gregory Forbes reports, to the centre of the petrous bone, and the other passing into the meatus externus. The edges of the main line of fracture are, in one part, widely separated, extensive absorption of bone having taken place, and the gap thus left is one inch and a half long, and the eighth of an inch wide at its broadest part. Mr. Tomes examined this preparation in its recent state, and found that there was no bony union even at the points, where the edges of the fracture were close to each other. In the second line of fracture, that passing into the meatus, the edges are in close contact, and apparently united by inlaid bone, the line of injury in this part being scarcely perceptible. The inner surface of the bones is, in some parts, roughened by the deposit of new bone in the neighbourhood of the lines of fracture. The case has been fully reported by Mr. Gregory Forbes (c), who presented the preparation to the museum of St. George's Hospital.

The third preparation (d) was taken from a man, aged 46,

who died in St. George's Hospital, of extensive ulceration of the stomach. Three years before his death this man, it appeared, had been pitched from his horse on to the back of his head, the results of which were a severe scalp-wound, and delirium for several days after the accident. In this preparation a distinct line of fracture can be traced through the left side of the occipital bone, from the upper part down to the point where the groove of the lateral sinus terminates in the jugular foramen. In its upper part this extensive line of fracture is closely united by inlaid bone; externally there is merely a linear groove, and internally the union is even more perfect, the line of fracture being visible here and there only. All this part of the bone is very much thickened, and extensively perforated by minute holes, some distance even beyond the line of injury. In the lower half of the fracture the edges of the bone are thin, and bevelled off by absorption; here there is a slight gap, which, in the recent state, was filled up by dense, fibrous tissue. At the end of this fissure, just where the groove for the lateral sinus terminates in the jugular foramen, the bone looks as if it had been broken up into several pieces. The union is perfect, but the lateral sinus is at this spot all but obliterated, and the occipital is here ankylosed, on the one hand, to the petrous bone, at the jugular articulation, and, on the other hand, to the atlas, at the condyloid articulation.

The fourth preparation (e) was presented to the College Museum by Mr. Henry Lee. It was taken from a man, aged 46, who lived a little more than seven months after a severe injury of the head, with bleeding from the ears, nose, and mouth. He was killed on the spot by a second injury, involving the upper part of the spine. The preparation shows a line of fracture, passing nearly straight downwards through the squamous portion of the right temporal bone, to the upper margin of the meatus auditorius externus; thence it proceeds along the upper wall of this passage, a part of the anterior wall being destroyed; and opposite the cavity of the tympanum it branches in two directions; by one of these branches, the fracture extends through the posterior and lower border of the petrous portion of the bone into the jugular fossa, which it completely traverses; by the other, it extends along the upper surface of the petrous bone, and ends in the hiatus Fallopii. That part of the fracture which lies in the squamous portion of the bone is, with the exception of a few minute apertures, closely and smoothly united; but in the part which traverses the petrous bone, there are only two or three small points at which union has taken place. At the upper surface of the base of the petrous bone, there is a considerable loss of substance, leaving a large hole leading directly into the cavity of the tympanum. The margins of this hole, and the bone around, are smooth and rounded off, as if from absorption.

The fifth (f) preparation belongs also to the College Museum. There is no history of the case; but this skull, it is thought, was removed with several others from the burial-place of some establishment for invalid soldiers in Germany. The occipital shows, on its left side, an extensive fracture, of an oval shape, passing from the upper part of the bone to within a short distance of the foramen magnum. At the lower part, there is a considerable displacement of the fragments, some of which have slipped downwards, and overlap a large portion of the outer surface of the bone. The displacement of the fragments has left, at the upper part, two irregular openings, the margins of which are smooth and bevelled off. The fragments are all solidly united to each other, as well as to the surface of the bone with which they have been brought into contact.

The sixth preparation (g) is in the Museum of St. Bartholomew's Hospital. The history of the case is unknown. The squamous portion of the temporal bone was smashed, and a line of fracture extended through the meatus externus, and base of the petrous bone, nearly as far as to the edge of the foramen magnum. The fragments in the one part, and the line of fracture in the other, are united firmly, but with intervals of non-union.

I must not leave the subject of fractures of the bones of the skull without adverting to an injury which sometimes

co-exists with these fractures. I allude to the separation of the sutures.

A question has arisen whether a separation of the sutures can possibly occur, without the bones being, in some way or another, broken. As might well be supposed from the nature of the articulations about the skull, a separation of a suture without a fracture is indeed a very rare form of injury. For my own part, I have, however, observed it once. It occurred in the posterior part of the squamo-parietal suture. The temporal having been slightly separated from the parietal and driven upwards, these bones presented, at first sight, the appearance of a fracture with depression.

In every other case in which I have met with a separation of the sutures, it has always been in connexion with extensive fractures stretching into the base. Thus, in seventy-eight cases of fractured skull, there were fourteen cases in which there was extensive separation of the sutures, two or more of which were sometimes implicated at the same time.

As to the frequency with which the various sutures give way, an analysis of these fourteen cases proves that separation of the coronal suture occurred in seven cases; in the lambdoid, it occurred in six cases; in the sagittal, in four cases; in the petro-occipital, in one; in the temporo-parietal, in one; and in the spheno-parietal, in one. It sometimes happens, when several sutures have given way, at one and the same time, that a whole bone becomes detached from the other bones. Thus, in one case, where there was complete separation of the coronal suture, the frontal was, at the same time, extensively separated from its connexions with the other bones of the skull, and thus all but isolated.

This separation of the sutures is, as a matter of course, most likely to occur before the adult period of life, and when the bones have not yet been soldered together. It has, however, happened at an advanced period of life, as proved by a case of Morgagni's, in which the patient was 60 years of age.

Co-existing, as this separation of the sutures for the most part does, with extensive fracture of the base, this injury must be classed among the most dangerous to which the skull is subject. It invariably indicates that great violence has been done to the bones. Oftentimes it is accompanied by laceration of the pericranium, and separation of the dura-mater; sometimes even by extensive laceration of both these membranes, through which the brain-substance has been squeezed out of the skull, and found lying immediately under the integuments.

Disjunction of the sutures is, then, always to be looked upon as peculiarly dangerous, not so much on its own account as on that of the extensive and serious injury of the other important parts with which it is generally associated.

It sometimes happens, however, that even a most extensive separation of the sutures, with fracture of the bones, is unaccompanied by any injury of the cerebral substance. Of this the following is a most remarkable instance:—

A lad, aged 17, fell from a tree a height of fourteen feet, and was admitted into St. George's Hospital, in a state of extreme collapse, from which he gradually recovered, so as to be perfectly sensible. The accident was followed by intracranial mischief, and he died in fourteen days. A fracture, beginning at the anterior part of the sagittal suture, passed through this suture in its whole length, and, having reached the lambdoid, deviated a little to the left, whence it coursed along the occipital bone, and terminated at the back part of the foramen magnum. In the whole length of the sagittal suture the two parietal bones were widely separated from each other, and on a different level. The left was in its natural position, but the right was driven down about two lines in its whole length. The brain itself was perfectly healthy. Extensive suppuration existed between the bone and the dura-mater, and there were some traces of inflammation both within the arachnoid and in the sub-arachnoid tissues.

Connected as a separation of the sutures is, all but invariably, with extensive fractures, its symptoms naturally fall into those which we have already fully examined; and so, too, does the treatment of such cases naturally fall into that of the fracture, whatever that treatment may be, which the case seems to require.

And now I proceed to a subject intimately connected with fractures of the skull, and one which of late years has become of great importance, as a means of diagnosis of these fractures.

As an accompaniment of severe injuries of the head, we

now and then find a watery fluid issuing either from the ear, or from the nose, or from some part of the vault of the skull.

The first notice of this watery discharge in connexion with injuries of the head is to be found, it is said, in Berengarius Carpensis, so far back as the year 1518; but, in truth, it is impossible to make out that the half-dozen words, so often referred to, have any connexion with our present subject. A most clear account of this watery discharge was, however, given by Stalpartius Van der Wiel, who, in the year 1727, published two cases wherein large quantities of a thin watery fluid had escaped from the ear for several days, after a severe injury of the head.

The first case, which fell under the notice of Stalpartius himself, runs thus:—

"One Ann Paulus, living at the Hague, was struck on the left parietal bone with a wooden staff of the size of a Belgian nine-pin, and so severe was the blow that she at once fell senseless to the ground. She vomited, and a small quantity of blood flowed out of the left ear. Called in consultation with James Sena, the Physician, and Arnold de Wilde, the Surgeon, Stalpartius found merely a contusion, but no fracture of the skull. Bleeding, and all other remedies usual in such cases, were had recourse to, and the patient gradually came to again; but for four or five days there escaped from the left ear a watery fluid, in quantities sufficient to have filled about a couple of pints I think; for a great number of towels were daily soaked through with this fluid. And yet the patient soon recovered her usual health."

The second case Stalpartius quotes from Joël Langelottus.

A prince, having fallen down a staircase, at Rome, a height of about 14 feet, pitched on to the left side of his head, and remained nearly a whole day perfectly senseless, and as if dead. After blood-letting, however, he in some measure recovered; but he then began to suffer so much pain in the head, that he got no rest, either by night or by day. All other remedies having failed, the Surgeons were about to resort to trepanning, when a gentleman of the household, who was standing by, observed a watery fluid running from the prince's left ear. The operation was therefore deferred, and so great was the quantity of fluid which escaped, that it was thought to amount to 8 lbs. in weight. No mention is made as to the ultimate issue of this case.

These two cases are the only ones usually referred to, as having been observed by the older Surgeons; but you will find in O'Halloran, some thirty years later, a case of the same nature, and in some respects even more characteristic.

In 1760, O'Halloran was called to a gentleman who had been thrown from his horse, and pitched on the right parietal bone. When picked up, he was quite insensible, and, in this state, he remained until his death, which took place five days after the accident. O'Halloran was especially struck by a constant oozing of a clear, limpid water from the right ear, which had come on immediately after the accident. The quantity of water thus poured out amounted to at least 12 ounces in the 24 hours. The discharge was constant, and continued so up to the time of the patient's death. He was scalped, but as no trace of injury was detected, it was thought that there was neither fracture, nor fissure. O'Halloran concludes by saying that he was very curious to open the head, in order to trace any possible source for this extraordinary discharge of water from the ear, which he never met with either before or since. Unfortunately, however, the family would not hear of any examination being made.

The elder Dease appears also to have been well acquainted with the occurrence of this peculiar watery discharge from the ear, as well as with its dangerous nature, which, however, he somewhat overrated.

In Colles' Lectures, edited by Mr. M'Coy, the following passage occurs in the lecture on fractures of the cranium:—

"The elder Mr. Dease believed there were certain cases of injury of the head which never recovered. I do not recollect whether it is in his work, but I remember he used to mention in his lectures a case which you may all have seen. As a patient with one of those injuries lies in bed, it will sometimes be perceived that the external auditory canal is filled with a clear lymph, which rises to a certain height, but does not overflow. You get a bit of sponge and *sup up* this as far as you can see, but the ear again quickly fills, and this happens as often as you may try the experiment." Mr. Dease believed that cases such as these never recovered, and was evidently not acquainted with the case of Stalpartius.

It may seem strange that facts so striking in their nature, and thus forcibly told, should subsequently have been lost sight of, but so it was.

Within the last twenty years, however, few indeed are the points in connexion with injuries of the head which have received so much attention from Surgeons, as this watery discharge has; and no point has called forth such minute dissections, or such elaborate investigations.

By some carefully made dissections, M. Laugier soon brought to light the co-existence of this watery discharge from the ear with a fracture of the petrous bone, and a rupture of the membrana tympani. And then followed the question, even now so much debated, as to the possible source of this fluid.

(To be continued.)

## ORIGINAL COMMUNICATIONS.

### ON THE RESTORATION OF MOTION

BY THE

### RUPTURE OF THE UNITING MEDIUM OF PARTIALLY ANCHYLOSED SURFACES.

By BERNARD BRODHURST, Esq.

Assistant-Surgeon to the Royal Orthopaedic Hospital.

(Continued from page 552.)

ANCHYLOSIS of the hip causes more inconvenience than of any other joint, except that of the maxilla. When ankylosis has taken place in the extended position of the limb, the patient can only sit on one buttock, with the leg of the affected side thrown backwards. Pressure on the buttock soon becomes painful, and the leg of the affected side is cramped. Consequently, sitting is an awkward, and after a time, a painful position. But the most painful position is on horseback. Not only is the seat most insecure, but it causes much pain, which is felt especially on dismounting. Three of the cases on which I have operated have been of mounted officers; and although in two of these only partial motion was restored, the relief was in both instances very great. One of these gentlemen writing to me some few weeks ago, said:—"I am in the saddle all day, and have no pain." The chief complaint of two other gentlemen also, who were similarly affected, was that in consequence of the pain produced they were unable to sit on horseback. The relief which seems to be most appreciated is that arising from the ability to flex the thigh, and consequently to sit fairly and straight on a chair. This position before the rupture of the adhesions was impossible; and it causes great satisfaction and pleasure to find that the power has been regained.

#### PARTIAL ANCHYLOSIS OF THE HIP-JOINT.

Case 1.—March, 1856.—L. S., 13 years of age, light-haired, and of a strumous complexion, was attacked with inflammation of the hip-joint three years prior to the above-mentioned date. She was attended at the commencement of the affection by a Surgeon in the neighbourhood of the metropolis, and was actively and very judiciously treated. Pain, however, was scarcely alleviated by the treatment: suffering was very great; the nights were passed without sleep, and the health had become seriously impaired.

When I first saw her pain had entirely ceased, and had not been felt during the preceding four months. The hip-joint was fixed, and without motion, at such an angle that, standing upright, the toes of the affected limb could just touch the ground, the heel being raised; the pelvis was very oblique; the spine was slightly curved; the right buttock was flattened; the limb was wasted: it was, however, by measurement the same length as the other.

Having fixed the pelvis with one hand, I suddenly flexed the thigh, jerking the limb, without using much force. The adhesions were soft, and yielded readily. Very slight pain followed the rupture. A gutta-percha splint was applied, and was not removed for eight days, at the expiration of which time passive motion was instituted. At first gentle movements only could be borne; but they were gradually increased, until the limb could be perfectly flexed and extended.

For six weeks after the rupture there was scarcely any voluntary power of flexion of the thigh, notwithstanding that tenderness on motion had ceased. From this time, however, motion began to increase, so that in the course of another six weeks there was considerable power of voluntary motion. Obliquity of the pelvis was in great measure overcome, and the sole of the foot was in contact with the ground. The foot could now be thrown well forward in walking. Five months after the operation the thigh could be flexed without assistance beyond a right angle, and it could be fully extended; the pelvis had regained its horizontal position, and the foot could be well flexed in walking.

In March, 1857, this patient walked with a stick, but firmly.

March, 1858.—In regard of size and firmness the two limbs were nearly equal; the buttock also had nearly regained its normal size. A stick was used for support when she walked to some distance from home; but in the house it was not now used. All the motions of the hip were perfect, and they could be employed unaided, except extreme flexion of the thigh. This thigh could not be flexed so perfectly as the other.

Case 2.—J. M., an officer in a cavalry regiment, early in the year 1854, in India, joined a shooting party, and having been for some days on marshy ground, was attacked with rheumatism, and had to be carried home. He remained confined to bed for three months, suffering acutely, so as not to have been able to change his posture during the early period of his illness. A large bed-sore formed over the sacrum, and effusion was so great around the hip that suppuration was feared. Happily, however, swelling subsided; but it was found when motion was at length attempted that the hip was fixed and immovable. Several months elapsed before he was able to resume his regimental duties, and then he found the fatigue of walking excessive, and his seat in the saddle most insecure; he also suffered excruciating pain on dismounting. These circumstances induced him to return home, for which he obtained leave.

March 5, 1857.—He walked into my room, leaning on a stick. I found the thigh fixed in the extended position, and immovable at the hip-joint; the extremity was of the same length as the sound limb; the pelvis was slightly oblique. I proposed to give chloroform, and to proceed to rupture the adhesions at the same time, should they be found to be fibrous. To this he assented, and the following day was appointed for the examination.

The full effect of chloroform having been obtained, the pelvis was firmly fixed by an assistant, when it was immediately apparent on endeavouring to raise the leg from the bed that the adhesions were fibrous. A jerk in the direction of flexion was sufficient to separate them, and the rupture took place with an audible snap. The motions of the joint were immediately free. The limb was then bandaged, and encased in a splint, and thus it was allowed to remain undisturbed for five days. Very slight pain was felt after the rupture, so that opiates were not required. On the sixth day passive motion was commenced. Only very gentle and limited movements were at first permitted, for considerable tenderness in the joint was complained of on moving the thigh. This tenderness, however, soon ceased to be felt, or the pain was not more than could easily be borne, and the splint was discontinued on the fourteenth day. After six weeks the thigh could be raised unassisted to a right angle with the trunk, and the limb could be fully extended: extension was executed slowly, but flexion by twitches rather than by a steady muscular action. The obliquity of the pelvis was entirely removed. The patient could walk without limping and without support for some steps if he walked slowly; he could also sit flat on a chair, and he could even straddle across a chair, sitting in the centre of the seat; but both of these positions were painful, and the latter could only be borne during some seconds. Passive motion, especially of flexion and abduction, was continued vigorously for several months; and, indeed, until the present time it is carried on daily. Now he can mount his horse comfortably, and can remain in the saddle, he says, "any number of hours," and has no pain on dismounting, but stiffness only. The motion of the joint is not so free, however, as I could wish to see it; but I have little doubt that whatever rigidity yet remains, will be in time removed.

Case 3.—F. C., 25 years of age, an officer in the Royal

Artillery, suffered, whilst he was stationed in Ceylon, from rheumatism, in 1855. He was confined to bed during many weeks, and suffered excruciating pain. Several joints were inflamed, as the shoulders, knee, hip, and ankle, but all recovered well except the hip. The effusion around the hip was more than about any other joint, and the swelling was so considerable, that it was feared suppuration would take place. However, it subsided, and at length it was discovered that the motion of the joint was lost. He returned to England some few months later, and consulted a Surgeon of the highest eminence, with a view to regain the motion of the joint. No hope was held out that motion could be restored, but on the contrary, he was assured that he must take his stiff joint with him to the grave. And in consequence he abandoned all hope of accomplishing his object. He was unable to perform his military duties satisfactorily, and he therefore now determined to leave the army. He expected to receive his captain's commission from day to day, and he proposed then to sell out.

At Christmas 1856, he heard of a case somewhat similar to his own, where I had ruptured the adhesions and restored the motion of the joint; and by the advice of Dr. Wood he in consequence came to me. I found both lower extremities of the same length; the head of the femur in its normal position; the buttock much flattened, and the limb slightly wasted. The limb was extended, and there was no power of flexion, nor of motion at the hip-joint, except a very slight (just perceptible) lateral motion. This motion, slight as it was, was sufficient indication that the adhesions were fibrous; and I gave an opinion in accordance with this view, and stated that the adhesions might be ruptured, and that the power of motion might be restored. He was about to proceed with troops to Canton, but he was anxious to have the operation performed before he went on board ship. I stipulated that I should have the power of watching him for six weeks after the operation. He was unable to promise this, however, as it was doubtful when he might receive orders to embark. The operation was therefore deferred until his return from China. Ten days later he embarked, expecting to leave the port on the following day, when an order was received to detain the vessel for three weeks. He immediately obtained leave of absence, and returned to London. The operation was done the day next but one following.

January 24, 1857.—The full effect of chloroform having been obtained, I fixed the pelvis with one hand, and with the other jerked the limb, without exerting much force, two or three times, when the adhesions yielded and gave way gradually, allowing the thigh to be flexed to its full extent. A gutta serena splint, which had been previously prepared, was then applied, and the limb was bandaged. On recovery from the effects of chloroform, my patient could scarcely believe that the operation had been done. He had no pain. Slight tenderness was felt in the course of the evening, but he slept well at night without an opiate. He remained in bed during the four following days, at the end of which time the thigh was slightly flexed, and again extended. After two more days the splint was discontinued. The limb was now moved every day, the joint being worked gently, and to a slight extent only at first; but soon more violent and extended movements could be borne, and ropes and pulleys were used. A stick was at first used for support in walking about the house, but it was soon discontinued, for he could walk firmly and without lameness. Beyond the house, however, a stick was used for some weeks. Before three weeks had elapsed, he had walked two miles from his lodgings. I was alarmed when I heard what had been done, and feared for the result; but, happily, no harm was done. Some slight tenderness of the joint and rigidity of the limb followed; it passed away, however, rapidly, and after twenty-four hours the motion of the limb was as perfect as before. Six weeks after the operation the thigh could be flexed voluntarily beyond a right angle, and it could be abducted to within one inch of its normal range of motion. To show how sound the joint had become, I may mention that my patient could sit on his heels, each heel being equally in contact with the corresponding tuberosity of the ischium.

March 21.—Exactly two months after the operation, the communication, to which I have already alluded at the head of this paper, was read before the Royal Medical and Chirurgical Society, and by his own desire this gentleman was present. Many then had an opportunity of seeing him walk

and some also were there who were well able to judge of the change which had been effected, having seen him previous to the rupture. He walked without the slightest halt, and without support. I received a letter from him, dated December 24, 1857, from which I quote the following sentences:—

"I walk occasionally twelve or thirteen miles a day; not bad, I think. The buttock has filled out wonderfully."

He was then, and had been for some months, performing his military duties. Now, I am glad to say, he has gained his promotion; and yet, I am more glad to add, he has no intention of leaving the army.

*Case 4.*—June, 1853.—A. G., 7 years of age, a small, ill-nourished, irritable, dark-haired child, suffered two years before this period from acute inflammation of the hip-joint, which was thought to be rheumatic in character, and which had followed exposure to wet and cold. When I first saw this child the thigh was flexed at a right angle with the trunk, and it was immovable. Under the influence of chloroform just perceptible motion could be obtained. A sudden jerk ruptured the adhesions with an audible snap, when the entire range of flexion and extension was immediately gained. Some pain was felt during that and the following day, to allay which opiates were given. Afterwards pain was felt only when the joint was moved. This tenderness lasted for ten days. After this time the limb was moved every day, and each day a more extended range of motion was gained; also the child was encouraged to move about the house, that the limb might thus be brought into action. Voluntary power was gradually, but slowly, developed. The limb remained very feeble during several months.

In this instance the limb was much wasted; it was, however, of the same length as the other limb. It was evident that infantile paralysis to a slight extent was superadded to rheumatic inflammation, and that some of the muscles, especially the extensors of the leg, had lost their power of action. Myogenic paralysis is not uncommon in childhood. I have only observed it in two instances, however, combined with partial ankylosis. Stimulating liniments, galvanism, and other excitants were used, while the limb was moved daily, to insure the freedom of the joint.

After two years the thigh could be raised beyond a right angle with the pelvis, the leg could be thrown forward in walking, and a stick only was used for support.

August, 1857.—The limb had nearly recovered its normal size; the buttock had filled out, though it was yet somewhat flattened; the motions of the hip-joint were perfect; and in walking about the room feebleness was not observable. After taking more than slight exercise, however, drooping of that side was apparent. No support was used. Stimulants were continued. There is little doubt that the power of the limb will be in time restored.

*Case 5.*—May 1856, H. S., 12 years of age, light-haired, with a florid complexion, was attacked with inflammation of the hip-joint after sitting on a damp bank, two and a-half years before I saw her. She suffered acutely when inflammation was first developed, and was treated at the time actively, yet it produced only partial mitigation of suffering. This acute pain lasted nearly six months, when it began to diminish, and ceased entirely about ten months from the commencement of the attack. The thigh had become flexed upon the pelvis during the period of confinement to bed at an acute angle; the pelvis was very oblique, and the spine was curved laterally; the heel could barely reach as low as the knee of the opposite side; the buttock was much flattened, and the muscles of the limb were wasted, but the limb itself was not shortened.

The adhesions, which appeared to be extra-capsular, yielded readily on the application of two or three sharp jerks, suddenly and completely. The limb was then bandaged and placed in a gutta-percha splint, and so left perfectly at rest for a week. A very slight degree of pain followed the operation, and even when slight movements were commenced, on removing the splint, they were scarcely complained of. In the course of three months, the thigh could be flexed and extended passively to the full extent of normal motion, little or no pain being excited; there was very little muscular power, however: the patient could walk across the floor with a stick and a crutch, and without dragging the leg, but without lifting the foot. Stimulating liniments were used, and a small blister was occasionally placed behind the trochanter. A visible effect was produced in the course of some

months, for muscular power was sensibly increased; yet progress was slow. In the summer of 1857, the thigh could be flexed, though not fully, and the patient could walk without other support than a stick. The obliquity of the pelvis had been entirely overcome, as well as the lateral inclination of the spine, without any special treatment being directed to either. Also, the tendo-Achillis, which was extremely tense, yielded and allowed the foot to be well flexed in walking. At the present time a stick is used in walking, except in the house. There is much muscular power wanting, and I doubt if it will ever be perfectly regained.

20, Grosvenor-street.

(To be continued.)

## RADICAL CURE OF A DOUBLE INGUINAL HERNIA.

(WUTZER'S METHOD.)

By REDFERN DAVIES, M.R.C.S.

William Gardener, aged 24, a labourer, and in the most perfect state of bodily health, has been the subject of hernia on the left side since birth; the hernial mass gradually increasing, is now about the size of a goose's egg; it is intestinal only; and is easily and completely reducible. On the right side a hernia has existed for three years, caused by a strain, in size about a hen's egg, and like its fellow, returned with facility and completely on April 16, 1858.

The patient lying on his back, the bowels having been well cleared out, the parts shaved, and the hernia reduced on the left side, Wutzer's instrument (as made by Ferguson of London) the "plug" being well smeared with Ung. Iyctæ, was applied.

The testicles were supported upon a soft cushion, and the handle of the instrument, by its own weight tilting downwards and rolling about, was also made to rest upon a support, and was confined to the thigh.

During the first 24 hours some mention was made of the pain caused by the blistering of the surfaces of the invaginated portion of integument, and some serous fluid flowed away.

On the 4th day after operation there were some swelling and tenderness around the invaginated plug, and a little purulent discharge.

On the 11th day the instrument was removed.

During the whole period of its application the patient had not experienced one half-hour's discomfort, much less pain (save from the blistering); and, upon examination, the following was the condition of the parts:—

April 27.—On the surface of the abdominal walls, through which the needle had passed for a space of a shilling, there was a superficial ulceration, the parts looking quite healthy.

Along the track of the inguinal canal the invaginated portion of scrotum could be felt distinctly and separately from the surrounding parts.

Around the invagination, extending for a distance of two inches, the parts had a faint blush, were swollen, thickened, and somewhat tender on pressure.

A pad and spica bandage applied, and the patient was ordered to keep his bed for a day or so.

On May 2, all tenderness and swelling having subsided, the right side was operated upon by an instrument exactly similar to the accompanying engraving, though larger:—

In this case the instrument was, as before, applied, but for only eight days. On removal, a similar state of parts was found, save that the intensity both in degree and extent to which the inflammation had extended was somewhat greater.

Pads and a spica bandage were applied; and he was allowed

to get up and go about the house in two or three days, when a double well-fitting truss was applied.

*Present condition*, May 30, 1858.—The patient was examined carefully by my father, Dr. Birt Davies, and Mr. Vose Solomon, in company with myself; when we found that cicatrisation had occurred at the points of exit of the needles, and complete union of the edge at the mouth of the doigt de gant, the only vestige of operation or deformity being the resultant cicatrix. In the inguinal canal a firm plug could be felt extending to the external ring, blocking it up completely. Upon coughing no impulse or descent of intestine could be felt, and we all thought the success of the operation was complete.

*Observations*.—During the progress of the first of these two cases I was led to observe some few mechanical imperfections in the instrument used.

Firstly.—The handle to the instrument was, by its length and weight, cumbersome, tending to tilt the parts downwards (a), which therefore required to be supported. To remedy this I substituted a button A, which fulfils all the purposes required of it, viz. to push the needle through the integument, and then subsequently withdraw it.

Secondly.—The putting a cap over the point of the needle.

These modifications I would submit are preferable to those of Mr. Spencer Wells, who removes both the handle and point, after applying the instrument, inasmuch as they are simpler, and less likely to get out of repair.

Thirdly.—The substitution for the upright stand of German silver at the end of the instrument the moveable piece C, whereby greater power, and more uniformity of pressure can be exercised.

(It should of course be moved up to as far as the edge of the invaginated portion, and then duly tightened.)

Fourthly.—By displacing all ornamental but not useful bits of plate, the price of the instrument is necessarily reduced.

Birmingham.

### ATTEMPTED SUICIDE WITH STRYCHNIA.—TREATMENT WITH NICOTINE.—RECOVERY.

By THOMAS O'REILLY, M.D., M.R.C.S. Eng.

On Thursday, September 10, 1857, at one o'clock p.m., I was urgently requested by Dr. Byrne to accompany him to see a Mr. Johnson in this city (St. Louis, Missouri, U.S.), who, he was informed, had taken poison. On arrival at his residence we learned the following history to account for his condition:—

After a three years' cruise, as a musician on board an United States frigate, he was paid off in New York, and for the amount purchased drafts on St. Louis, which, on his arrival here were found to be worthless. This, together with recent domestic sorrows, so overwhelmed him, that he determined on self-destruction. To accomplish this end, he called on a respectable druggist, and demanded a large dose of poison for a dog. The druggist gave him six grains of strychnine, which he carried into an adjoining beer-house, and, playfully remarking to the bar-tender that he was going on his last spree, mixed the strychnine with beer, and drank it off. Soon repenting this rash act, he mentioned to those present that he had taken poison, and wished they would give him an emetic. One was procured which vomited him freely, but, notwithstanding, violent symptoms set in, and we were called on to see him.

On entering his room we found him stretched on his back, his countenance expressive of the most painful suffering and distress, his frame shaken by frequent convulsive spasms, his limbs rigidly extended, and his head slightly bent backwards. His face was of a livid red, and covered with a profuse sweat; his eyes were sunken, and moved with a rapid motion; his mouth was covered with saliva, which he ejected by spasmodic jerks, strongly reminding me of a case of hydrophobia which I had seen some time before. His respiration was quick and difficult, and attended with great pain in the precordial region; skin warm, and covered with a profuse

(a) In Wutzer's instrument the handle can be removed.—Ed.

clammy sweat, and he had copious watery discharges from his bowels. His intellect clear and collected, and his feelings were so morbidly acute that the slightest touch appeared to aggravate his sufferings, and to bring on a spasm. On this account we could not correctly ascertain the state of his pulse.

Ignorant of any antidote likely to relieve him, and pressed by the urgency of the case, Dr. Byrne, acting on the suggestion of Dr. Haughton's paper (read before a meeting of the Royal Irish Academy, Nov. 29, 1856), took a cigar from a gentleman present, and infused it in half a pint of water.

One hour and fifteen minutes after he had taken the poison we gave him the first dose of the tobacco infusion, which he swallowed with difficulty. We continued it in table-spoonful doses at intervals of five minutes, until he had taken half the quantity infused, before we had noticed a favourable change. Then the muscles became relaxed, the spasms less severe, and the intervals between them longer; and so conscious was the patient of relief, that he constantly called for the tobacco-juice when he felt the paroxysm approaching. This encouraged us to persevere with the infusion, prolonging the intervals between each dose, as the frequency of the spasms abated; until finally, after twelve hours, they disappeared, leaving him in a state of fearful nervous prostration, from which he recovered in a few days, under a careful tonic treatment.

In the quantity of infusion administered we used one ounce and two drachms of dry tobacco leaves, including the cigar—a quantity which no healthy condition of system could stand; but the urgency of this case demanded it, and the result justified it, and at the same time afforded us another illustration of the counteracting influence of poisons, and tended in some way to establish the correctness of the conclusions at which the Rev. Mr. Haughton had arrived by his experiments.

From a single instance like this, I should be far from recommending nicotine as an antidote; but I trust that the publication of the case may attract the attention of others, who will test the subject with due care, and give the result of their experience to the world.

St. Louis, Missouri, United States.

### OBSTINATE OPHTHALMIA TARSI,

TREATED BY THE APPLICATION OF TINCTURE OF IODINE  
AND GLYCERINE.

By ANGUS MACMILLAN, M.D. etc.

M. A., aged 12 years, five years ago had a severe attack of scrofulous ophthalmia. On examination we observed specks on both cornea, and considerable conjunctival vascularity. Edges of eyelids much inflamed, hardened, and considerably thickened; eyelashes agglutinated together. Partial obliteration of Meibomian apertures in right lower eyelid. General health evidently much impaired; skin and digestive organs disordered, and undoubted marks of a scrofulous constitution present.

On being questioned, stated she had been under treatment more or less since the attack of scrofulous ophthalmia, that general and local means had been employed, but with no permanent benefit.

The edges of the eyelids were washed carefully, and any adherent matter removed from the roots of the eyelashes and Meibomian apertures. The edge of each eyelid being carefully everted, the tr. iodine was then applied to the whole edge by the aid of a fine camel's-hair brush, which was passed over two or three times, so that the tr. iodine might enter the Meibomian apertures, and be diffused among the cilia. During the day and night frequent application of the glycerine by the aid of a common camel's-hair brush. In the course of two or three days a decided improvement was manifest. Three more applications of the tr. iodine at intervals of three to four days sufficed to cure the case. Quinine and sulphuric acid were administered internally.

Many more cases followed by the same success could be reported, but the above will be sufficient to direct attention to this mode of treatment of an affection of the eyelids which in a majority of cases may be considered incurable. I am not aware that this method has ever been previously suggested; and should any of your readers feel disposed to give it a trial,

it is to be hoped they will communicate the result of their experience so that its true value may be ascertained. The tr. iodine is a more convenient and effectual application than the ordinary salves, inasmuch as its stimulating properties can be brought to bear more directly on the Meibomian apertures. Hull.

THE LONDON  
PRACTICE OF MEDICINE AND SURGERY.

THE ROYAL LONDON OPHTHALMIC  
HOSPITAL.

MR. CRITCHETT'S NEW OPERATION FOR  
DISPLACING THE PUPIL.

About a month ago we noticed very briefly a new operation which Mr. Critchett had devised for displacing the pupil, and which had then only been practised in about half a dozen cases. The plan has since succeeded so admirably in such a numerous series, that it may now be considered an established procedure. We must, accordingly, not delay longer to bring the details of its performance before our readers. At first mention, the idea of drawing out a fold of iris tissue in such a manner as to leave the pupillary margin itself free, and of then securing it from return by the application of a ligature, may not sound like a very practicable one. That it is easily so has been fully proved by the practice not only of Mr. Critchett himself, but of more than one of his colleagues. As stated in our former notice, the cases for which this mode of operating is especially required are those in which a limited leucoma constitutes the hindrance to vision, and in which the pupil is free from adhesions. We will suppose such a case on the operating couch. The steps of the operation are then as follows:—With a broad needle an incision is made through the edge of the cornea at the side selected, just large enough to admit of the introduction of the canula forceps. The latter instrument is then passed into the anterior chamber, and made to seize the flat surface of the iris, at a distance of about a third of the breadth from the cornea to its pupillary border. The iris thus doubled on itself is drawn out of the wound. With another pair of forceps, ready armed with silk, the operator now seizes the prolapsed portion, upon which the ligature is next placed, and tied by his assistant. In tying it two pairs of broad-pointed forceps must be employed, instead of the fingers, and some delicacy is required. The instrument here shown is the forceps

which Mr. Critchett has had made for the purpose of holding the prolapse during the application of the ligature. The blades are broad and well bowed, so as to throw off the ligature easily, and for the purpose of retaining it during their application a slender steel leg is fitted on each, the points of which, although just in contact, are of course not united to them. The silk used should be fine, but soft, and not tightly twisted. After being tied, both ends may be cut off close. There does not appear to be any tendency to draw the prolapse in again; indeed, the peculiar way in which the folds of iris are secured by the ligature prevents any traction being exerted in a direct line inwards. The ligature usually drops off in a day or two, and the wound rapidly heals. As far as we have observed Mr. Critchett's cases, singularly little irritation follows the operation.

A case of conical cornea in a young woman under Mr. Bowman's care, in which it was desired to make a narrow elliptical pupil in each eye, afforded a very instructive contrast of the new plan with that of cutting out a portion of cornea. Mr. Bowman operated on the left sides of each eye on the same day, in the one adopting the ligature plan, and in the other cutting away a small portion of cornea, and leaving the iris to prolapse, and acquire adhesions to the cicatrix. In the latter, the wound was long in healing, and

was attended by very much more of surrounding inflammation. In operating on the right sides of the two eyes, a fortnight later, Mr. Bowman employed the ligature in each, and was much pleased with the result. Indeed, the wound made by cutting out of cornea on the first occasion was not soundly healed until some time after the whole of the other three.

It is to be observed that the method by cutting out a little bit of cornea is almost the only one which aims at exactly the same result as Mr. Critchett's, i.e. the displacement of the normal pupil, not the making (by laceration or cutting) of a new one. In most of the others the iris is seized at its pupillary margin, and its structure lacerated, or if no pupil exist an entirely new one is made by a cutting needle. The advantages in all cases where possible of leaving the pupillary border uninjured has long been acknowledged, and its supposed impracticability alone prevented its being much more frequently adopted. If in the attempt to apply a ligature to the iris in the manner above described, the Surgeon should, as will sometimes happen, be unable to limit the amount of prolapse, and include in it the margin of the pupil, he has but converted his operation into one of the old kind, and has only defeated one part of his purpose.

HOSPITAL NOTES.

CASE OF SUCCESSFUL OVARIOTOMY.

A case in which a good recovery followed the extirpation of an ovarian cyst has recently occurred in Addenbrooke's Hospital, Cambridge. The operator was Mr. Humphry. The patient, a woman, aged 22, tall and well made, was admitted with ovarian dropsy of five years' standing. She had been twice tapped, and on one occasion the injection of iodine had been practised. As the cyst had refilled ovariotomy was decided upon. The incision made was nearly four inches long, in the median line, and below the umbilicus. Two large utensils full of fluid were evacuated, and the cyst with some difficulty was then drawn out. No adhesions existed. The pedicle was broad and short, and was tied in four parts. The ligatures were brought out at the lower part of the wound, the upper portion of which was closed by sutures. No ill symptoms followed, and she left the hospital, well, within six weeks of the operation.

PARALYSIS OF THE FACE CAUSED BY CANCER  
OF THE PHARYNX.

Dr. Risdon Bennett has recently had under his care in St. Thomas's Hospital a man, who presented a somewhat unusual group of paralytic symptoms. He was a weaver, aged 45, and of spare habit. He had in the first instance complained of pain above the left ear, and in the neighbouring parts. In a short time he became deaf on the left side, and then the left cheek and temporal region became numb. There was at this time no muscular paralysis. Subsequently, however, the tongue became divergent to the left side, and at length much difficulty was experienced both in speaking and swallowing. The tongue was complained of as feeling larger than natural, and the left pupil assumed a state of permanent contraction. He emaciated gradually, and at length sank. At the autopsy a growth of epithelial cancer was found involving the pharynx, and extensively destroying the base of the sphenoid bone. It had ulcerated into the throat, but not very widely. The brain itself was healthy, and the paralysis had evidently resulted from the involvement of the nerve trunks.

DEATH AFTER PARACENTESIS OF AN  
OVARIAN CYST.

It is very desirable to bear in mind that the tapping of ovarian cysts, especially for the first time, is a procedure far from being devoid of danger, since the fact bears with much importance on the question as to the propriety of other and more radical methods of treatment. The statistics of this operation, usually deemed so simple, have not hitherto been collected on a sufficiently extended and trustworthy scale, and it is therefore desirable from time to time to put individual instances of fatal consequences prominently forward. One such has recently occurred at St. Thomas's Hospital. A married woman, aged 30, was admitted on account of a large ovarian tumour which distended the abdomen. It had existed nine months, and had followed three months after childbirth.

She was considerably reduced in health, but there did not appear to be any condition forbidding the employment of the trocar, from which, on the contrary, much relief was expected. The operation was performed by Mr. Woakes, one of the House-Surgeons, and about a painful of thick fluid removed. The tumour was reduced in size, but a considerable bulk still remained. The woman gradually sank afterwards, and died exhausted on the fifth day.

#### DIVERGENT STRABISMUS.

We adverted a few weeks ago to two cases of divergent strabismus, under Mr. Critchett's care, at the Moorfields Ophthalmic, the subjects of which were a father and daughter. In each the degree of divergence, which was great, was almost exactly similar. The father had, however, contracted his; but in the daughter the deformity was congenital. An unfavourable prognosis as to the results of the ordinary operation was, therefore, given by Mr. Critchett in the latter case. The operation was performed on both patients on the same day, and consisted in the division subcutaneously of both external recti. The father's eyes remained perfectly straight afterwards; but, as had been feared, the girl's were in the course of a fortnight almost as widely divergent as ever. Under these circumstances, Mr. Critchett determined to adopt a procedure for bringing forward the attachments of the internal recti, which we have several times before seen him perform, and which we described in these Reports about four years ago. The patient being under chloroform, with scissors and forceps the conjunctiva of the inner side of the globe was divided at about a quarter of an inch distance from the corneal margin, for a length of three-fourths of an inch. The dissection was continued inwards, until the internal rectus and the adjacent fascia and cellular tissue having been freely divided, the first third of the inner side of the globe was cleared, and a considerable flap, consisting of muscle, conjunctiva, and intervening cellular tissue turned inwards. Sutures were now passed through the whole of this flap, half an inch from its free margin, and again through the narrow attachment of conjunctiva at the edge of the cornea. A curved portion of the flap (at its deepest part fully the third of an inch wide) was next cut away, and the sutures were then tied across. This had the effect of drawing the eyes very much inwards, giving a very decided internal squint. Three sutures on each side had been employed. When we last saw the patient, there was still a slight degree of internal strabismus; but as the tendency would no doubt be towards the production of the original divergence, the eyes will, in all probability, be straight in the course of a few months. Even should they not, however, their present condition is very greatly preferable to the state of things before the operation.

This operation (a) is like many others of those performed on the appendages of the eye, not nearly so difficult to perform as it may, we dare say, strike the unpractised reader of our description. It is one which can be most confidently recommended for bad cases of divergent squint, whether the result of previous operations or otherwise. Cases of divergence are, we may again remark, attended by infinitely more of disfigurement, and are at the same time far more difficult to remedy than those of convergence. For the latter *subconjunctival* myotomy, as practised at Moorfields, realizes everything that can be expected of a surgical procedure, and very rarely indeed requires any modification.

#### OVARIAN DROPSY TREATED BY THE INJECTION OF IODINE.

The practice of treating ovarian cysts when single by the injection of iodine seems to hold its ground, and, indeed, to decidedly gain in favour. Dr. West and Mr. Paget, who, in St. Bartholomew's, have, we believe, had a larger series of cases than any other of our London men, have obtained results which have been on the whole quite satisfactory. The reader must not from this suppose that any cases have been cured off hand by a single injection. In almost all more than one injection has, we believe, been required; in several the treatment, although repeated to a third or fourth, did not seem to have much effect; and in the best all that ought perhaps to be asserted is, that the secretion has been arrested. In a disease in which the radical method of treatment, and the results of non-interference are both so formidable, the simple arrest of

the tendency to refile, even if the tumour be not wholly got rid of, is a very satisfactory attainment. Very probably additional experience may much assist us in the details of this method of treatment, and enable us to secure a greater proportion of cures. In most cases we believe it has been the practice to employ a very dilute tincture, and in large quantities; but it may be fairly open to question whether this is the best. In a case recently treated by Dr. Ramskill and Mr. Hutchinson in the Metropolitan Free Hospital, a concentrated solution was employed, and allowed to remain in. The injection was practised twice, with an interval of about a month; and on each occasion after the cyst had been as completely drained as possible, a scruple of iodine, and half a drachm of iodide of potassium, dissolved in an ounce of water, constituted the injection, and was wholly retained. The reasons which induced Mr. Hutchinson to employ so concentrated a solution, were, first, the belief that what was wanted to prevent re-secretion was destruction of the epithelial lining membrane of the cyst by iodic cauterisation, and that the stronger the fluid the more certainly would this be effected. Secondly, the hope that so concentrated a solution would be less likely to be absorbed quickly, and might therefore be left in to produce its full effect with greater safety. Thirdly, the consideration that however carefully an ovarian cyst be drained, it is almost impossible to empty it, and that therefore a dilute solution is yet further reduced by mixture with the remaining fluid. Fourthly, that it is not desirable to introduce so much alcohol into the system as is contained in from half-a-pint to a pint of tincture. With regard to the results in this case we may state that on neither occasion did any alarming symptoms follow, and that although four months have elapsed since the last injection, the patient remains quite well, no tendency to refilling being manifested. Before the treatment tapping had been repeatedly practised, and was required every six weeks or two months, as the cyst was very large, and refilled very rapidly. The injection treatment is of course applicable only to monocystic cases, and if employed in others might very probably irritate adjacent cysts not injected, and do more harm than good.

#### THE HOSPITAL PHARMACOPŒIA.

(Continued from page 508.)

To continue our comments upon the therapeutics of the Hospital for Skin Diseases, we may remark that an undisturbed faith in the *efficiency of the long-continued use of mercury in small doses, for the cure of various chronic inflammatory affections*, is a very important item in Messrs. Startin and M'Whinnie's successful practice. What, if rightly looked at, are many of the constitutional forms of skin disease, but chronic inflammation of the integument; more or less, and often less rather than more, peculiar in its character? If a sore, with indurated swollen edges, like certain lupus ulcers, were discovered on the os uteri, what constitutional treatment would suggest itself? A mild mercurial course, and the use of caustics *topically*, would probably be what most judicious practitioners would advise. Under it he would expect to see the oedema of surrounding tissues disappear, the edge of the ulcer soften down, and granulations show themselves. What is the impediment to the healing of chronic ulcers on the leg but inflammation; aggravated, let it be granted, by the peculiarities of the circulation of the part, but still in essence inflammation? We are well aware that such ulcers may be cured most satisfactorily by attention to local conditions only; but that constitutional measures are also very efficient, even when almost unaided, no one who has attended the practice of this Hospital can doubt. Although not usually classed among skin diseases, yet this Institution has obtained a very extensive reputation for the treatment of ulcers of the leg, and numerous sufferers from them attend there. Many of the cases are very bad ones. Mr. Startin always directs the patient to bandage the limb, but no very particular attention is devoted to this part of the treatment. Internally, the mixture *hyd. comp.*, the formula for which we gave in our last notice, is mostly ordered, and to the sore itself the *unguentum rubrum* (see page 503) is applied. If the ulcer is sloughy or very unhealthy-looking, the acid nitrate of mercury is applied as a caustic, previous to the use of the ointment. These cases are never taken in, nor are the patients directed to confine

(a) An account of it is given in Mr. Dixon's admirable work on "Diseases of the Eye." Mr. Dixon warmly recommends it.

themselves to bed; and from the rapid healing which often ensues, we cannot but think that the mercurial medication, both internal and local, has usually a considerable share in the cure. In Lupus, Mr. Startin almost always orders either the calomel and opium pill, or the mercurial mixture, usually combining the former with the simultaneous use of cod-liver oil. In estimating the effect of the mercurial in these cases, and, in attempting to explain it, it must always be remembered that a taint of hereditary syphilis may possibly be the real cause. There can be little doubt but that in a considerable proportion of cases such is the fact, and that the Surgeon who prescribes mercury, may possibly eradicate a specific virus; while in others the beneficial influence of the mineral must be attributed to its general efficiency against all kinds of chronic inflammation. To take, again, acute eczema—can there be any doubt as to the inflammatory nature of the diathesis which attends well-marked cases? They are such as, under the old regime, would have been deemed to require bleeding; and when, even now, that expedient is resorted to, a cupped and buffed condition of the blood usually bears out the practice. In these, Mr. Startin almost always orders the bichloride mixture, with the addition usually of from five to ten minims of colchicum to each dose. Now and then salivation will unexpectedly occur; and the irritation will often subside most rapidly on slight ptyalism being induced. Another class of cases in which, contrary to the generally received doctrine, Mr. Startin often orders mercury, are those of so-called "scrofulous" character. Cases of gland disease in the neck, with extensive ulceration of the adjacent skin, often present themselves; and others of what is termed "cutaneous struma," a form of primary ulceration of the integument, occurring in feeble young persons, and distinguished by its undermined non-indurated edge from true lupus. In these, the internal use of calomel and opium in minute doses, and with cod-liver oil, is almost invariably ordered. We have watched cases in which patients, suffering from strumous disease of the cervical glands and skin, took calomel once or twice daily for many months under Mr. Startin's care, and not only without injury to their general health, but with decided benefit to it, and with exceedingly favourable results as regarded the local disease. To the sceptical on this subject we must recommend Dr. Wilson Phillip's little book on the use of minute doses of mercury, and we may also venture to make reference to the writings of Abernethy, Tyrrell, Carmichael, and others.

## Medical Times & Gazette.

SATURDAY, JUNE 12.

#### THE MEDICAL REFORM BILL.

ONE of the many advantages of a constitutional and independent House of Commons is that freedom of discussion which characterises debates in the British Parliament. Be a subject ever so obscure or impracticable, repeated discussion amid the advocates of opposed interests is certain eventually to eliminate something clear and workable. The Legislature has—session after session for the last thirty years—had a measure before it for altering and amending the laws relating to the Medical Profession; but each year as it expired found

the Medical Reform Bill not only unpassed, but the whole subject enveloped in greater difficulties and obscurity than ever, from the conflicting interests of the existing Medical bodies. During the last twelve months, however, a great advance has been made towards a proper understanding of the question of Medical Reform in all its bearings, both in Parliament, the Profession, and the country generally. The eloquent speech of Lord Elcho last session was the starting-point of the advance, and the very lucid exposition of Mr. Walpole last week showed how carefully the new Home-Secretary had studied the subject, and how able he was to enlighten Parliament on what he held to be the true principles of Medical Reform. Never before have we seen honourable members so interested in Medical Reform as on the last debate, and their constant turning over of the pages of the three bills while Mr. Walpole made his analysis of them, showed an earnest desire to gain information, and understand the subject thoroughly, which indicates a speedy arrangement of the difficulties, should the present Parliament remain undissolved.

The principles laid down by Mr. Walpole as being important to hold in remembrance in legislating on this subject were, *Reciprocity of practice with recognition of all existing institutions; registration; and a supervising or controlling authority.* These three principles, if properly and fairly carried out, will without doubt satisfy the members of the Profession at large, and will probably interfere the least possible with existing bodies. We still feel convinced, however, that the one portal plan of admission to the Profession as embodied in the bill of the Select Committee, and which need not be, nor would have been, a *minimum* examination in the perverted sense of that term, would have done more for public good and professional advancement. The numbers of men of merit practising in London who have enrolled themselves as graduates of the London University, although by so doing they attained no legal status as physicians, is evidence enough that men of talent are not insensible to pure honorary distinctions; and we may rest assured that the "Licentiates in Medicine and Surgery" of Lord Elcho would not have rested satisfied with what only entitled them to registration. Since Lord Elcho has withdrawn his bill, however, and we are to have the bill of Mr. Cowper amended in committee by Mr. Walpole as representing the present Government, it behoves us to watch over the reconstruction of the clauses, and see that they shall operate with the least possible partiality towards either the Royal Colleges or Universities, and the present and future holders of their respective diplomas. All persons who know anything of the subject are fully prepared for the attempt which will be made by the Colleges to modify the clauses of the Bill in such a way that the Universities may be deprived of their right to license, and this power be conferred only on the Colleges. The Colleges of Physicians have intimated in plain terms that they will be parties to no legislation which does not confer this power solely on themselves. Of course if the College in London or Dublin believes that it alone should possess this privilege, it has a perfect right to such opinion; but we strongly deprecate the inconsistency which drew down upon it the keen censure of Lord Elcho on Wednesday week. It would appear from the Noble Lord's speech, as reported in the *Morning Post*, that the College of Physicians,—as a body-corporate not liable to, or in favour of changes generally—has altered its opinion at least three times in the last two years as to the constitution of the Council, according as the proposed Bill suited its yearnings after increased power, or the contrary. In 1856 it recommended a Crown-nominated Council to the Select Committee; it 1857 it opposed this as a fatal objection to Lord Elcho's Bill, and recommended the representative Council of Mr. Headlam's Bill, the latter giving them unlimited power at the expense of the Universities. In this

year of our Lord 1858, Mr. Cowper's Bill, which does not confer exclusive privileges on the Corporations, is opposed by the College, because, forsooth, the Council (being representative like Mr. Headlam's) "represents so many conflicting interests." Hence Lord Elcho's inference that the constitution of the Council is not a matter of importance to the College, but is simply made a pretext for opposition to any Bill which does not specially serve its purposes.

We cannot conceive on what pretext the Colleges base their affected superiority to the Universities. The examinations of the London, Edinburgh, and Dublin Universities seem as much esteemed as their own; that of the London University being even superior in every respect; while St. Andrew's, which has been held up as an example of an inefficient University, has lately introduced a practical test of competency at the bedside into its examinations, which the London College of Physicians cannot boast. The old story that the Colleges alone represent the Profession we have previously disposed of by showing that the members and licentiates have no voice whatever in the Councils. We find it still urged, however, that it is not desirable for candidates to be examined for degrees, as in the Universities, by the Professors who teach them; and this is employed as an argument against the continued power of the Universities to license. Now this argument might have weight were it proved that no teachers or professors occupied places at the examining boards of the Royal Colleges; but it is notoriously the fact that perhaps the majority of examiners in these Colleges are also lecturers in some one or other Medical School.

The objections to Mr. Cowper's Bill, which led us to prefer that of Lord Elcho, may be met by certain modifications in the former Bill as it passes through Committee. It may reasonably be doubted whether the powers conferred on Mr. Cowper's Council are not too arbitrary and extensive. If the Council had simply the power of a veto in any new arrangements where the licence to practise is concerned, or where any body is inefficient in its teaching and examinations, the power conferred on it would be enough for every needful purpose, and it would probably work very effectively. And further, it is very desirable that the form of register to be kept henceforth should be made the subject of a special clause. It should be simply alphabetical, with the qualifications following the name, instead of leaving the form of register to the discretion of the Council. Should special registers be adopted, and each class registered separately, the Colleges might endeavour to make capital even out of this, and declare that Medical University graduates have no title to be registered either as Physicians or Surgeons, and are not, therefore, eligible for public appointments.

The Committal of this Bill has been deferred until next week, when we may expect renewed discussion. In the meantime we again insist that, in the event of the Medical Reform Bill being postponed for another Session, by far the best course to adopt will be the appointment of a Royal Commission of Inquiry into the whole subject.

#### NEW SALE OF POISONS RESTRICTION BILL.

THE Sale of Poisons Bill is again attracting public attention. The Bill has been read a second time in the House of Lords, without discussion. We gather from what has transpired, that Lord Derby has endeavoured to effect a compromise with the chief opponents of the measure, namely, the Pharmaceutical Chemists, and that the Bill now before the House of Lords is the result of this arrangement. It is said to be founded on the recommendations of the Committee of last session. The Royal College of Physicians and the Pharmaceutical Society have been required to give their opinions on the proposed clauses, and where these bodies have agreed, the amendments have been adopted; but where they have differed,

the Minister has followed the provisions of the old bill. Any remarks that we may at present make would be almost premature, because it is highly probable that the Bill, if it pass the House of Lords in its present shape, will undergo some alterations in the House of Commons. It may be observed, however, that the exigencies of trade appear to be such, that Lord Derby has found it impossible to place any restrictions on the sale of laudanum, opium, tartar-emetic, and chloroform. These articles may be procured for the purposes of suicide or murder, as heretofore. We presume that they may be sold to children at the discretion, or indiscretion, of the vendor,—and in the absence of a witness, or even of any registry of sale. The "quietness powders" (consisting of tartar-emetic) sold by the druggists of Bolton to wives who had grown tired of their husbands, may still be procured without let or hindrance. The case of murder, which was tried at the Liverpool Assizes in 1856, and drew from the learned Judge some strong remarks on the open sale of this substance to children, and on the necessity of legislative prohibition or precaution, is allowed to pass without warning. For some reason, which we have not been able to discover, persons of all ages have such urgent necessity for the purchase of small quantities of tartar-emetic, that to prevent the sale of it by an ignorant boy to a child more ignorant than himself, and to require a registry of such sale, would, to use Lord Derby's words, "altogether destroy certain branches of trade, and prevent the transaction of legitimate business."

We gather from a report in a contemporary journal (a), that the druggists wished to erase oxalic acid from the list of substances to be restricted. But this was resisted by the College of Physicians. The twenty thousand druggists, grocers, oilmen, and hucksters, who at present deal in poisons, have their interests equally secured, whether educated or uneducated, whether members of the Apothecaries and Pharmaceutical Societies, or self-styled chemists and druggists without a knowledge of chemistry or drugs,—their vested rights are not to be touched. As a class they must die out; and until this generation has passed away we must be prepared for the annual average of deaths from poison, arising from the incompetency and ignorance of three-fourths of the number who now legally sell and dispense poisons. Those who propose to deal in poisons, if not members of the two Societies above mentioned, will, after a date to be fixed by the Act, be required to undergo an examination as to their competency. It is on this point that the Royal College of Physicians and the Pharmaceutical Society are at issue. The grounds of this difference of opinion are thus stated by Mr. Jacob Bell on the part of the Pharmacutists:—

"The Board of Examiners proposed, was to consist of three persons,—one from the College of Physicians, one from the Society of Apothecaries, and one from the Pharmaceutical Society: all Apothecaries and Pharmaceutical Chemists to be exempted from this examination. On the subject of the proposed Board of Examiners, he thought the Pharmaceutical Chemists must make a stand, because if the permission to deal in those articles were to be given by a Board constituted by Government on a lenient examination for a small fee, it would naturally draw a number of persons to that examination who did not correctly understand the distinction between such a qualification and that of a Pharmaceutical Chemist, and prevent them from coming for examination to the Society, the object of which was to raise the qualification of Pharmaceutical Chemists as much as possible. A certificate considered by many probably as good, if not better than their own, would, in many instances, no doubt divert the applicants from that channel of education they were creating, and therefore it was to the interest both of Pharmaceutical Chemists and the public, that the Council should well watch the pro-

(a) Pharmaceutical Journal, June 1, 1858, p. 565.

ceedings in contemplation for the adoption of this new Board, and obtain for the Pharmaceutical Society the privilege of examining those parties who might require a license for the sale of poisons" (b).

On this we have to remark, that the examination is *not* to be conducted by a "Government Board;" but, as Mr. Bell properly states in the first sentence of the quoted paragraph,—by a Board appointed by the College of Physicians, the Society of Apothecaries, and the Pharmaceutical Society itself! Surely the interests of the Society will be sufficiently protected by the appointment of one examiner out of three; and we cannot concur in the view that the interests of the public will suffer by the substitution for a Physician and Apothecary of two members of the Pharmaceutical Society. For what reason the examination is described as "lenient" we do not know; the smallness of the fee (if this be already fixed) will rather affect the pockets of those who receive it, than the interests of the public. The fees paid by candidates for degrees in the University of London are comparatively small, but the examination is more stringent than in institutions where the fees are much larger. The fact is, a number of persons may probably select this poison-qualification in preference to that of the Pharmaceutical Society; but this is taking entirely a six-and-eightpenny view of the question. Our impression is, that the privileged sale of the very few articles restricted by this Bill, will scarcely furnish an inducement to undergo the proposed examination, to persons seeking to enter the drug-dispensing business. They will by law have a large range of business still thrown open to them, without examination and without restriction; and of this it is probable they will take advantage, either by not procuring the license, or by setting up in business if rejected as incompetent. They will balance the profits derived on the sale of opium, laudanum, and tartar-emetic, against those which might have been derived from the sale of arsenic, oxalic acid, and strychnia; and in the end they may sustain no loss. How much the public are likely to gain by the new measure we are unable to state at present; we must wait, as we have already stated, until the Bill reaches the House of Commons, and has undergone full discussion there, before we can form a conjecture on this point. The list of restricted poisons may be increased, diminished, or otherwise altered. Mr. Duncombe may, from conscientious feelings, propose to insert lobelia in place of oxalic acid, or to exclude the Coffinites, like the regular Apothecaries and Pharmacutists, from the operation of the measure!

#### THE WEEK.

Sir Philip Crampton died at 20 minutes before 10 on Thursday forenoon. We have only space this week to express sorrow at his loss. Next week we shall give some account of his Professional career.

The departure of the *Niagara* on an experimental cruise for laying down the Atlantic Telegraph wire, has been preceded by the usual exchange of dinners. One of them on board the *Impregnable* at Plymouth, led to an exchange of civilities between the Medical officers. The American officer spoke highly of the services rendered by us to their squadron during a late epidemic of yellow fever in the West Indies; and Dr. O'Hagan, of the *Impregnable*, proposed the health of Dr. Green, and the Medical officers of the United States Navy, in an eloquent speech. He made some amusing allusions to the first Naval Surgeons—or Surgeons to the Naval Brigade—at the Siege of Troy, Podalirius and Machaon; showing that our Army and Navy Medical brethren were as

little kept back from the post of duty and honour by any consideration of personal safety in ancient as in our own times. "We have never hung in the rear when we could be of service in the front, and Machaon must have been pretty well in advance when he was wounded by the side of that unrelenting warrior, Idomeneus."

A full report will be found in another column of the important meeting of the supporters of the Medical Benevolent College. We have received a letter from Mr. Cattlin on the part of the dissentient Governors, again asserting that the discussion was improperly checked; but as we feel assured that the Council just elected will fully consider every proposition brought before them for the good of the College, we most earnestly advise all well-wishers to the Institution to work together cordially in peace and unanimity for the good of the common cause.

Mr. Owen Rowland has drawn attention to the state of London roofs as a source of disease. He says:—

"Within the last twelve months, in ascertaining the feasibility of establishing telegraphic communication between police and fire stations upon an overhouse system, I have ascended and traversed some hundreds of roofs, and upon several occasions I have found heaps of animal and vegetable matters as well as stagnant water (in consequence of defective gutters), etc., lying upon the roofs and emitting the most offensive smells, which in time, by percolation, no doubt saturate the walls of the houses to their very foundations, to the great injury of the health of their occupants."

We, long ago, pointed out how this might be remedied, and the London roofs converted into a series of gardens or promenades by a small smoke rate. Instead of ugly chimneys, we should have ornamental arcades formed by large and small smoke ducts converging towards district smoke-consuming furnaces, and it would be very easy to bring ventilating shafts from the sewers into the same ducts. The smoke rate could not possibly be so heavy as the sewer rate, yet it would effectually remedy the smoke nuisance, and make the atmosphere of London as clear as that of Paris.

An Appendix to the Report of the Army Sanitary Commission has just appeared. It consists of copies of letters written and received by the Director-General and officers of the Army Medical Department, relating to the health of the troops in Bulgaria, the Crimea, and Scutari during the war in the East, 1854 to 1856. It contains no less than 976 letters or memorandums, commencing with the Director-General's preliminary sanitary inquiries and measures in Bulgaria and Turkey, instituted in February, 1854, and all the sanitary correspondence relating to the troops and hospitals in Bulgaria, the hospitals on the Bosphorus, the state of Balaklava and the camp before Sebastopol, and the hospitals and transports, to June, 1856. No stronger proof could possibly be afforded of the truth of the statements we have so repeatedly made, that the Medical Department, so far from being held responsible for our disasters in the East, would have entirely prevented those disasters, had it been possessed of sufficient authority to enforce attention to its instructions. As early as April, 1854, Dr. Smith urges a provision of clothing adapted to Turkish winters. Sir C. Yorke replies that it is impracticable to make any changes, and that the Commander of the Forces will give such orders as he deems expedient. In May, 1854, Dr. Smith makes suggestions for sick transports, hospital marquees and accommodation, which if acted upon at that time would have prevented the fearful mortality in the troop ships which took place six months later. Indeed, on looking over the letters every one must admit that from

(b) Pharmaceutical Transactions, June, p. 585.

Dr. Smith downwards the whole department was constantly endeavouring to preserve the health and promote the comfort of the soldiers, while their advice was too frequently disregarded by those in authority. Unceasing care and foresight on the one hand, too often met by indifference on the other, are the characteristics of the correspondence, and the key to our misfortunes.

Mr. Witt has just published a letter to Mr. Simon on the use of Ammonia in Scarlatina and Measles. Mr. Witt looks upon the treatment by ammonia in these diseases as a specific, as much so as quinine in intermittents. The late Mr. Wilkinson stated that Dr. Peart had introduced the remedy, and did not lose one patient out of three hundred cases of scarlatina; and Mr. Wilkinson adds that for seventeen years he has never lost a patient from this disease, nor ever had a case that even appeared dangerous. Mr. Ricardo, who attended many large schools, had not lost a single patient out of some hundreds during twelve or fourteen years. The dose is from three to seven grains every hour for the first twenty-four hours, and every second hour for the next day. All acid drinks are carefully avoided. This is a matter of interest just now that the power of ammonia in retarding coagulation of the blood has been established, and it is curious as an illustration of the success attending opposite methods of treatment; for the use of acetic acid in the treatment of scarlatina has been gaining ground very rapidly of late, and the success which has followed its use has been very great.

The Court of Examiners of the Society of Apothecaries has just issued the new Regulations for Students upon which we commented last week. The following are the regulations, which, it will be observed, only apply to Students who have not yet commenced attendance on Lectures:—"Every Candidate whose attendance on Lectures shall commence on or after the first of October, 1888, must attend the following Lectures and Medical Practice during not less than three winter and two summer sessions: each winter session to consist of not less than six months, and to commence not sooner than the 1st nor later than the 15th of October; and each summer session to extend from the 1st of May to the 31st of July. *First Year.*—Winter Session: Chemistry, Anatomy, Dissections. Summer Session: Materia Medica and Therapeutics, Botany, Practical Chemistry. *Second Year.*—Winter Session: Anatomy, Physiology, Dissections, Principles and Practice of Medicine, Clinical Medical Practice. Summer Session: Clinical Medical Practice, Midwifery and Diseases of Women and Children, with attendance on Cases (not less than twenty), Forensic Medicine and Toxicology, Demonstrations on Morbid Anatomy. *Third Year.*—Winter Session: Clinical Lectures (seventy-five), Clinical Medical Practice, Demonstrations on Morbid Anatomy."

The following amusing little history from the *Atlas* is a curious illustration of the ignorance of quacks and their dupes:—

"John Glen, an itinerant cleaner of clocks, was, in August last, dissatisfied with his business prospects. Being unable to read or to write, there were not many directions in which he could proceed in the hope of bettering his position. Though not a scholar, he was a shrewd fellow. In his Scottish rural perambulations he had noticed that people were more credulous as to curing bodies than clocks. He saw that as a Medical practitioner with a new system, he might make a good hit. His only misgiving was that Glen was not, perhaps, a faith-inspiring name. The couplet—

'Gin ye advise me to marry Tam Glen,  
I'll gie ye my bonnie black tappit hen.'

was, he probably remembered, familiar to everybody, and a

familiar name would of course impair his *prestige* as a great foreign Physician. He did not long hesitate as to the appropriate means of overcoming this difficulty, and adopted the cognomen of 'Dr. Willoughby and Sons,' as indicative of his claims to aristocracy and plurality. Having provided himself with printed handbills, announcing the therapeutic pretensions of Dr. Willoughby and Sons, of the Botanical College of Baltimore, he started upon a professional tour through the northern provinces of Scotland. These manifestoes were duly distributed in the various towns, villages, and farm-steadings on the eve of his intended arrival. They produced an impression decidedly favourable to the botanical Physician. This was a natural result, as they contained circumstantial and authenticated accounts of many wonderful cures effected by his medicines, after vain attempts by members of the regular faculty."

Then follow some singular details of family history which led to a trial at Perth and a conviction of the *Doctor* and his sister. They were convicted of "causing false entries to be made in the official register of marriages." The man was sentenced to eighteen months' and the woman to twelve months' imprisonment. Yet this man might have gone on levying contributions on the ignorant to any extent, had he only laid himself open to the charge of acting as a Medical impostor.

From a report published by Dr. M'William, and appended to the second Report of the Commissioners of Her Majesty's Customs on the Customs, we perceive that the average health of the inferior officers of the waterside and water-guard departments is very satisfactory; the number daily on the sick list in the landing department being only 1.43 per cent., and in the water-guard department, 2.80 per cent. Indeed, it appears that the mortality in the class over whose sanitary condition Dr. M'William so ably presides, is rather less than that of the male population of England between 25 and 65, which is the range of age of the Customs' officers; and much smaller than that of the foot-guards in London. The chief causes of extraordinary mortality among tide-waiters on board ship seem to be poisoning by carbonic oxide and carbonic acid from the combustion of charcoal, coke, and coal, when used for fires in cabins, galleys, or round-houses. Another cause of death is also mentioned, which nearly produced fatal consequences in the early part of this year, namely, the influence of the vapour emitted from damp grain; the gas chiefly developed in such circumstances being carbonic acid.

## THE LATE PROFESSOR MAUTHNER.

Louis William Mauthner was born at Raab in Hungary October 14, 1806; and arriving as a poor student at Vienna entered the Joseph Academy. After he obtained his degree he was appointed assistant in the Medical Klinik of that establishment. He highly distinguished himself during the cholera year, 1831; and after serving some time in the army he resolved in 1836 to devote himself entirely to children's diseases. A year later he opened a private children's hospital; and in 1848 was enabled by the contributions of several wealthy ladies to build and open the present St. Anne's Children's Hospital. In 1850 he was promoted from a *privatim docens* to be extraordinary professor of children's diseases. Not only did Mauthner establish the first children's klinik in Germany, but he also founded a nursery society for healthy children, and a Hospital for scrofulous children at Baden near Vienna. In consequence of his numerous services to humanity he had the order of the Iron Crown conferred upon him, and he was ennobled with the title of von Mauthstein. He was the only member of the present professional body that had received this honour. Although not qualified by disposition or ability to take the active part he desired in the scientific impulse that distinguished the Vienna school at that period, he was most laborious and able in carrying out his

mission of practical utility. Kind and indefatigable, he did not content himself with allowing the children of the poor to come to him, but himself sought for them, and ministered to their necessities in the most benevolent manner. He died in the prime of life, after a short illness, possessed of considerable property. He left to the Hospital of St. Anne 10,000 florins, and to its Klinik all his books relating to children's diseases, as well as his pathological preparations. The remainder of his library he bequeathed to the Medical Society.

## ROYAL MEDICAL BENEVOLENT COLLEGE.

THE adjourned Annual General Meeting of this College was held at the Freemason's Hall, on Tuesday last; the Earl Manners in the chair. There was a very numerous attendance.

The meeting having been formally opened,

MR. CATTLIN, in rising to propose a list of new members of Council, in opposition to the list proposed by the Council, said he could not expect that the facts and arguments which he had to submit would be fairly considered by the meeting, unless it was convinced that the dissentient Governors were influenced by very different motives from those of factions opposition. He regretted very much that such motives should be attributed to gentlemen who had no other object than to promote the welfare of the College, and whose only misfortune it was to differ in opinion from their brother Governors. (Hear, hear.) Surely, the members of a liberal profession ought to be liberal enough towards each other not to impute improper motives to those who differed from them. He (Mr. Cattlin) had done all in his power to avoid opposition, and he had proposed to the Council that five members should be nominated by himself or the dissentient Governors, and five by the Council, so as to obviate the necessity for a ballot; but that proposal was not accepted. He and those who acted with him were in no way hostile to Mr. Propert, but their desire was to benefit the College by the infusion of new blood into the management. That this was required would be tolerably obvious from the statement of accounts which had been prepared and distributed among the governors; and from which it appeared that the amount expended by the College had been £63,372. Of that sum, less than £3000 had been spent in the object which they all especially sought to promote, viz. the benefit of the poor of the Profession; and even that small amount had not been properly distributed. The exhibitors had been promised an education at £25 per annum, exclusive of books, but the charge had been raised to £40—a great disappointment to those poor Medical men to whom a cheap education for their children would be a great boon. It might be said that the Act of Parliament fixed the amount, but the opinion of Mr. Roundell Palmer had been obtained to the effect that there was no compulsion to make that charge, and even if there were it would be easy to get an amended act. There had been an obvious mismanagement and misapplication of the funds—of course he did not use the words in an offensive sense—for £60,000 had been expended in carrying out that which had been promised to the public for £18,000. Moreover, eighty-four residences for pensioners were yet unbuilt. Public confidence had been shaken, and it was of the highest importance to restore it by electing new members. The gentlemen whom he would propose would not be "factious," nor unduly wedded to their own opinions, but would, if elected, co-operate with the other members in all that was beneficial to the Institution. If the Council would now consent to receive three gentlemen whom he would nominate (three of the present Board retiring) he would withdraw the other names which he had to propose. Nothing, he thought, could be more conciliatory on his part than that offer.

MR. PROPERT declined the offer on the part of the Council.

MR. CATTLIN said there must now be an end of all charges of "factious opposition" against the dissentient Governors. He concluded by proposing the election of Edward Ballard, M.D., Myddelton-square; Charles P. Croft, M.D., Woburn-square; T. Blizard Curling, Esq., Grosvenor-street; John F. Harding, Esq., Pentonville; William Munk, M.D., Finsbury-place; Timothy Pollock, Esq., Hatton-garden; Richard Quain, Esq., Cavendish-square; Edward Ray, Esq.,

Dulwich; Joseph Ward, Esq., Epsom; John Warwick, Esq., Stamford-hill.

The following was the list proposed by the Council:—Henry Blenkarn, Esq., Dowgate-hill; T. Blizard Curling, Esq., Grosvenor-street; Robert Dunn, Esq., Norfolk-street; Richard D. Edgecombe, Esq., Shaftesbury-crescent; George Fincham, Esq., Marlborough-hill; Charles F. J. Lord, Esq., Hampstead; Richard Quain, Esq., Cavendish-square; Edward Ray, Esq., Dulwich; Henry Sterry, Esq., Paragon, New Kent-road; Joseph Ward, Esq., Epsom.

The Rev. Mr. WHITE, in seconding the proposal of Mr. Cattlin, after repudiating the imputation of being "factious," referred to a lithographed letter which he said had been issued by Mr. Propert, stating that if his list was not adopted he would retire from the institution. Every man, he said, had an undoubted right to think as he pleased, but he (Mr. White) considered that the issuing of such a letter was, to say the least, a great mistake in judgment. No one wished to deprive Mr. Propert of the influence which he possessed; but the institution was now a public one, and the members should be left free to exercise their own rights. He concurred in the observations of Mr. Cattlin as to the want of proper management and the misapplication of funds. As to the educations of the exhibitors, he was quite certain that £30 a-year would be quite sufficient for the purpose.

MR. HANCOCK, after thanking Mr. Cattlin for the temperate manner in which he brought forward his proposition, said the Council had been unjustly charged with obtaining an Act of Parliament that deprived governors of their legal rights, and with misapplying the funds entrusted to them; and the accusation had been supported by a number of figures which he should be able to show were extremely incorrect. The actual cost of the building to which reference had been made was £31,457 (exclusive of the chapel, which cost £3050), but it had been stated at £36,000. The law expenses had been set down as £1700 exclusive of the cost of the Act of Incorporation; and in that item alone there was a mistake of £500. The Act of Incorporation cost £611, and the total law expenses (including that act) down to a later period than had been mentioned, were only £1800. Nine hundred pounds had been spent in the enfranchisement of the land, and converting the copyhold property into freehold; and taking all the expenses into account, the land only cost the Society £140 an acre, while the freeholders of the surrounding ground were asking £250, exclusive of legal expenses. It had been said that by bad management in the investment of the funds £1160 had been lost. In the first place, he did not see how the Council of 1858 could be made responsible for the acts of the Council of 1851. That Council invested £13,000 in Consols; and were they not justified in so investing the money rather than allowing it to remain in the banker's hands? The present Council were only carrying out contracts previously entered into, and they had no power to alter them. As to new blood being introduced, there were now only four members of the Council who were on the Board in 1851, when the original estimate of £18,000 was put forth. The sum lost by investment was £1188, but no credit had been given for the dividends which the society had been receiving, amounting to no less than £1145. (Hear, hear.) The cause of the loss was the Russian war, and Mr. Cattlin might as well charge the Council with being the cause of the Russian war, as with having caused the loss of the amount in question. In his calculation of the amounts spent in charitable objects, Mr. Cattlin had omitted £500 or £600 for the clothing of the boys. £2708 had been spent upon the foundation boys, exclusive of pocket money, exclusive of their share of accommodation in the building, and exclusive of their participation in the £2800 expended in the purchase of land. As to the pensioners (who, it was said, only received £192), he would ask whether the £6250 spent for their residences should be left out of the question; and also the £1400 for furnishing, and the £3000 spent upon the chapel in the benefit of which they participated? Mr. Hancock then entered into details of account, contending that there had been no misapplication of the funds. He explained that since the original estimate bricks and other materials had increased in price, and that other institutions found themselves unable to provide a good education for boys for less than £40 a-year. He appealed to the meeting to support the Council, and put it in a position to complete the benevolent undertaking which had been commenced.

Mr. POWNALL expressed the pleasure which he felt in observing the spirit animating the meeting, and his hope that the Society would be united more firmly than ever. He moved that the ballot should at once be taken.

Mr. TOOME seconded the motion, which was carried by a large majority.

Mr. WARWICK desired to address the meeting in reply to Mr. HANCOCK, before the motion was put, but the Chairman decided that he was not in order in so doing.

Mr. WHITE and Mr. CATTLIN protested against the decision.

The ballot was then commenced, the Chairman observing that after it was concluded, gentlemen desiring to address the meeting would be at liberty to do so.

The members having voted, and the scrutators retired to prepare their report,

Mr. KESTVEN moved the following resolution:—"That it is the opinion of this meeting, that the Governors of the Royal Medical Benevolent College ought to have a larger voice in the management of this institution, and should have the power at general meetings, and upon giving proper notice, of bringing forward independently of the Council, such alterations in laws and by-laws, or other propositions, as may appear to be for the interests of the Institution; and, if that is necessary, that the Act of Incorporation, and the existing laws and by-laws, be amended accordingly." He maintained that the Governors had not a sufficient voice in the management of affairs; that they could bring forward no independent propositions, whatever abuses or corruptions might creep into the proceedings; and that the Council had a tyrannical power over the general body, quite inconsistent with the spirit of modern times, and at variance with the laws of most corporate bodies.

Mr. WARWICK seconded the motion, and referred to cases in which he said the Council had refused to bring forward motions proposed, and accede to requests made, by independent Governors. He said he had been unable to ascertain, from the accounts presented by the Council, the actual financial condition of the College; and it was high time that the Governors should have a more adequate power than they now possessed. It was said that the Act of Parliament prohibited such an arrangement; but if so, the Act could be altered so as to meet the views of the subscribers.

Mr. FULLER, in opposing the motion, said it was most fortunate that Parliament had given the power to the proper parties, and that, had it been otherwise, the College would constantly be in a toilsome sea of hot water.

Mr. WEBB maintained that the statements made as to the inordinate power of the Council were unfounded. There must, he said, be an executive, and its appointment was entirely in the hands of the Governors. The Council were but servants of the general body, which had the power of withholding its confirmation of any by-laws that the Council might have adopted, and of appointing any committee of inquiry that it might consider necessary.

Mr. CATTLIN said the principal thing complained of was that the governors had not the power to initiate by-laws.

Mr. YATES SMITH opposed the motion.

Mr. KESTVEN having replied, the motion was put from the chair, and was rejected by a large majority.

Mr. PROPERT intimated that a special meeting would be shortly held with a view of increasing the number of foundation scholars in the school from thirty-five to forty.

A vote of thanks was unanimously passed to Mr. Proport, who briefly acknowledged the compliment.

A vote of thanks was also unanimously accorded to the noble chairman.

The following was the result of the ballot:—

Mr. Curling . . . 245	Mr. Sterry . . . 200
Mr. Quain . . . 245	Mr. Dunn . . . 198
Mr. Ray . . . 245	Dr. Ballard . . . 46
Mr. Ward . . . 243	Dr. Munk . . . 45
Mr. Blenkarne . . . 201	Mr. Pollock . . . 45
Mr. Fincham . . . 201	Mr. Warwick . . . 44
Mr. Lord . . . 201	Dr. Croft . . . 44
Mr. Edgcombe . . . 200	Mr. Harding . . . 39

MEDICAL STAFF IN INDIA.—Dr. Mackinnon, formerly of the 42nd Highlanders, has taken Medical charge of the Head-quarters Staff, in place of Dr. Clifford, 9th Lancers, who is ordered to Landour.

## PROGRESS OF MEDICAL SCIENCE.

### Selections from Foreign Journals.

#### OBSERVATIONS ON THE DURATION OF PREGNANCY.

By Dr. ELÄSSER.

As a contribution to this subject, Dr. Elässer communicates the particulars of 260 cases of normal pregnancy with mature children, entered in the journals of the Stuttgart Lying-in-Hospital, and to which certainty may be attached.

1. <i>Reckoning from the day of conception</i> , the duration was—	
Exactly 280 days in	23
Less than " "	166
More than " "	71
	—160

In nearly one half (126) the duration was between 271 and 280 days, and in 62 other cases between 281 and 290 days.

Separating the cases into primiparæ and pluriparæ, we find that there were 149 primiparæ, and in these the duration was—

Exactly 280 days in	14
Less than " "	96
More than " "	39
	—149

In 111 multiparæ the duration was—

Exactly 280 days in	9
Less than " "	70
More than " "	32
	—111

So that among primiparæ there have been greater abnormalities in plus and minus, and the mean normal period has been seldom met with than in multiparæ. The extremes of the duration of pregnancy (232 days, and from 301 to 306 days) occurred in primiparæ.

2. *Sex of the children*.—The sex of the child seems to have exerted little or no influence upon the duration of the pregnancy. There were born 130 children of either sex; but as among the primiparæ a great preponderance of female (85) over male (64), happened to occur, the extremes of duration were met with in them.

3. *Reckoning from the commencement of the last menstruation*.—The indication of this is often wanting, or too indeterminate to be relied upon; and among these cases it could only be depended upon in 175. Of these 13 menstruated once after conception, and the reckoning in them was made from the penultimate menstruation. The duration was found to be—

Exactly 280 days in	12
Less than " "	43
More than " "	120
	—175

Of the last number the duration was from 281 to 290 days in 60, 291 to 300 days in 49, and 301 to 318 days in 11.

If 280 days be accepted as the normal duration, the reckoning from the date of conception more nearly approaches it (in 8.8 per cent.) than that of the last menstruation (6.8 per cent.) This so-called normal duration is, however, that which is seldomest met with; for reckoning from the period of conception 91.1 per cent., and from the commencement of the last menstruation, 93 per cent. of all the cases either fall short of or exceed this term. The same deduction may be drawn from the observations of others. Thus, Merriman found only 9 of 114 cases in which labour came on at the 280th day. Reid enumerates only 18 of 46 women in whom, conception following a single coitus, labour came on between the 274th and 284th day; and Duncan found, reckoning from the period of conception, 275 days, and from the last day of menstruation 278 days, was the mean period.

4. *The interval between the commencement of the last menstruation and conception* was found to be—

5 days in 13 cases	
From 6 to 10 " "	47 "
" 11, 15 " "	38 "
" 16, 20 " "	18 "
" 21, 25 " "	9 "
" 26, 30 " "	14 "
Above . . 30 " "	8 "
	—134

These statements are, however, to be taken with the greatest caution, for it is seldom that this class of women observe exactly the last day of menstruation.

5. *The weight of the child in relation to the duration of pregnancy.*—Dr. Elsässer furnishes a table in which the mean weights of the children are placed side by side with the duration of the pregnancies of their mothers; but we need not transcribe this, inasmuch as it only proves that there is no relation prevailing between the two facts.—*Henke's Zeitschrift*, Band lxxiii. pp. 394—400.

#### CASE OF ANURIA WITH PYELITIS AND THROMBUS OF THE RENAL VEINS.

By Dr. BRUNNER.

Valentin P., aged 65, hitherto enjoying good health, excepting that of late years he had had some difficulty in discharging his urine, towards the end of November began to suffer from retention of urine. The author was called in consultation November 30, and found that no urine had been passed during forty-eight hours. There was neither distension nor tenderness in the pubic region; but there was slight fever and some vomiting, together with some pain following the course of the right ureter. A catheter was easily passed, but not a drop of urine flowed away, a little blood alone issuing when the catheter was withdrawn. Believing some obstruction must exist high up in the urinary passages, possibly accompanied by inflammatory action, a treatment of an antiphlogistic and demulcent character was put into force. The introduction of the catheter was repeated daily, but with no effect, when in the night, between the 2nd and 3rd December, a spontaneous discharge of a quart of clear, almost colourless, strongly-smelling urine took place; and about the same quantity passed away twice within the next twelve hours. From the middle of December 3, another complete retention commenced, the catheter being introduced daily without effect. The right renal and inguinal region, which had become after the spontaneous discharge less painful and distended, again became sensitive and almost bolster-shaped, and frequent vomiting of mucus took place. The patient died comatose on December 8.

The autopsy was performed more than twenty-four hours after death. A strong, penetrating, urinous smell filled the room; the epidermis being easily separated, with urinary evaporation. The muscular coat of the bladder was found hypertrophied, and the organ itself, though dilated in size, was entirely void of urine. Its neck was very hyperæmic, the left ureter was obliterated throughout its entire length, and the left kidney was atrophied, being only  $2\frac{1}{2}$  centimetres long, 1 cent. 8 millim. broad, and in places scarcely a few millim. in thickness, forming a firm, shrivelled body with yellowish-white (calcareous) infarction. The blood of the vena cava was dark and clotted. The left vena renalis was filled with a dry, firmly adherent plug 1 centim. in length. The right ureter was obturated by fibrous exudation, its diameter being irregular in size in places. The right kidney was almost three times its natural size, its enlarged pelvis and calyces being in a state of inflammation. It was filled with turbid, flocculent urine, and its cortical substance was nearly white. The right vena renalis had throughout its course contracted strong adhesions with the neighbouring parts, and contained a compact, dark red, irregular, and slightly adherent coagulum.

Thus the cause of death in this case was atrophy of the left kidney, and pyelitis on the right side, together with obliteration of the left, and recent obturation of the right ureter. Whether the plugs in the renal veins are to be regarded as emboli, or, as is more probable, as isolated products, the imperfect examination permitted did not allow of determining. However, the autopsy shows that the left kidney having long since ceased to act, the right one had performed the offices of the two, until prevented by the supervention of inflammation. The urinous smell during the autopsy, and the comatose symptoms prior to death, lead to the belief that this was immediately induced by uræmia. The thrombus of the renal veins seems to have been of older origin, and may explain the difficulty in the excretion of the urine complained of by the patient during late years. The complete atrophy of the one kidney produced by the mechanical obstruction of the circulation, led to the excessive action of the other, whence ensued its hyperæmic condition with the consequent pyelitis.—*Würzburg Verhandlungen*, Band viii. pp. 146—160.

#### EXCERPTA MINORA.

*Unusual Contents of a Lachrymal Tumour.*—Dr. A. von Gräfe relates a case in which tumefaction of the lachrymal sac exceeded in size that of a large walnut. On its being opened, it was found to be filled with a dark brown substance, containing innumerable golden, shining, minute plates, giving all the appearance of metallic particles. Under the microscope these glittering bodies proved to consist of cholesterine, the crystals being of unusual size. Besides these, cells were found, abundantly filled with fatty granules, and dark red or orange-coloured nuclei, probably due to a preceding hæmorrhagic discharge into the sac. The walls of the sac were smooth, and its obliteration was procured by the actual cautery.—*Archiv. für Ophthalm.* band iii. p. 358.

*Hemeralopia.*—M. Netter, as the result of abundant observation and experiment, arrives at the following conclusions. 1. Hemeralopia is the reverse of nyctalopia. The cause of the first is an excess of light, and of the latter a prolonged privation of this stimulus. 2. When a subject of hemeralopia is brought during the daylight into a dark place, he remains unable to see there, although the persons who accompany him are soon able to distinguish all that surrounds them. Hemeralopia is not, therefore, a periodical blindness, coming on only in the evening. It is a blindness which prevails during imperfect illumination, whether in day or night. 3. It may be cured in a few hours. The patient going into a dark place in the middle of the day, should continually cast his eyes around him, forcing himself, so to say, to see. At the end of two or three hours the vision is restored, and the complaint is cured.—*Gazette. Med.* No. 20.

*Hypertrophy of the Mamma.*—Dr. Esterle relates a remarkable instance of this occurring in a young pregnant woman, the periphery of each breast measuring about 40 inches, while the distance from the nipple to the internal margin of the breast measured 15 inches, the areola presenting a radius of  $2\frac{1}{4}$  inches. The weight was calculated at 26 to 30 lbs. each breast. The pain was excessive, and no relief was obtained from depletory treatment and the use of iodine. Morphia alone gave palliatory relief until the delivery of a small child. After this, milk was discharged spontaneously, in great abundance at first, but soon ceased to flow. In five weeks one breast had diminished by a fifth, and the other by nearly a half, and the patient was enabled to leave her bed for the first time for nine months. While thus going on favourably, she was carried off by enteritis.—*Omodei Annali*, vol. clxii.

#### FOREIGN CORRESPONDENCE.

##### NATAL.

UMHLATI, April 2, 1858.

I was much interested by your editorial reports on the connexion between food and disease, embodying, as they do, more information than has yet been collectively published. Thinking that any trustworthy information in this line might prove acceptable to you, I wish to state that I have now witnessed for a whole year the innoxious effects on the human economy of the flesh of oxen the victims of pleuro-pneumonia—an epizootic in every respect identical with that prevailing in Europe, imported into this colony a few years ago from the Free-state on the other side of the Drakenberg. The animals stricken by this pestilence are invariably consumed by the Kafirs without any evil results, with exception of an occasional indigestion, which is, however, far easier explicable by the prodigious quantities of meat consumed by our black brothers at one *séance*, than by any noxious quality of the article. You really may say, without exaggeration, that Kafirs intoxicate themselves with beef, when they can get it; and particularly in a famine-year like the past has been, from failure of the maize, a lung-sick ox was not to be despised. Nor are they as particular about dressing this meat as a London butcher has good reason to be, but roast the ribs with parts of adherent pleuritic exudation mass undismayed. No condiment seasons the glutinous banquet, no salt, no Worcester sauce, no petite verre asserts its corrective influence, when the last bone is denuded

of its covering, the last millimetre of gut consumed. If they had received a classical education they would then, no doubt, offer libations out of their dirty calabashes, with the anything but limpid, but still wholesome water of these parts, to Apollo, the ox-killer, the pestilence-sender! Then the dakkahorn goes round; far milder in its effects than the Indian plant, for I see boys smoking without any visible effect beyond a glazed, swimming eye, and increased hilarity. Saliva is copiously secreted under its influence, which they emit through a slender reed, forming bubbling imitations of kraals and cattle on the ground,—a most æsthetic accomplishment, still more elegant than the practice of our Yankee friends, who pride themselves upon pasting flies at a yard's distance. But "revenons à nos boeufs." The dogs eat the diseased lungs—miserable starved curs as they are—with great gusto, and are none the worse for it. Fowls, pigs, and vultures, also seem to enjoy it without harm; although I must mention that an observant officer told me that when the epizootic raged near Maritzburg, in the North-west part of our colony, the carrion-birds left the carcasses untouched and disappeared for a time altogether. (?) Other causes may here have been at play. Of course I do not allow lung-sick meat to be issued to the troops, viz. the 57th men, I am considered capable of taking care of, and I inspect the lungs of every animal killed for their use. A form of lobular pneumonia in oxen ending in fatty or calcareous degeneration of the affected parts, does not seem to stand under the same epizootic influence as the pleuro-pneumonia; the finest animals are generally affected with it, and the meat unobjectionable. Preventive inoculation in the tail for lung-sickness is practised extensively; and although many beasts die from diffuse suppurative inflammation in the peri-rectal tissues, the protective influence is so undoubted as to render their losses of no account. Hoof and tongue-sickness are innocent, *quoad* the meat, the animals fall off from being unable to feed properly; milk becomes painfully scarce, and the cheese and serum cannot be perfectly separated from the butter, which forms a soft, unpleasant, and quickly rancidising mass. The experiments of Renault and Delafond you are of course acquainted with. According to Rosenthal, *Prague Journal*, 1855, ii., two persons (out of a number who partook of the same meat with impunity) were affected with fatal carbuncular disease after partaking of cooked *milt-brand* meat without having been in contact with the raw material. This fact is isolated. Can we be surprised that meat-poisons (which are of course destroyed by proper cooking) are common, when we consider that snake poisons and curarin even are taken into the stomach with impunity. Nor does any perfect integrity of the digestive organs seem indispensable.

I am repeating Cienkowski's (*Bull. de Petersb.* 1856) remarkable observations on the formation of a cell round amylum-granules in potatoes, allowed to rot in water. A cell-membrane formed around the starch-granules gradually increases in size, its finely granulated contents become separated into small round masses, which are metamorphosed progressively into cell-shaped bodies with two long cilia at one extremity. These have a rapid motion (are exactly in every respect identical with erratic spores of algæ), and bore their way through the cell-wall. A further development has not been observed. This is a most wonderful and inexplicable fact; a starch granule acting as a centre of attraction, playing the rôle of a nucleus; an individual vegetable organism resulting. The same granule can go through the same process repeatedly, but gradually appears to get corroded. No spore, no nucleus is visible in the granules. Is this spontaneous generation? I can only say it is the only fact known, as yet, inexplicable by any other theory. However, we may know more about it in time. I am making trials with different amylum sorts, allowing slices of cheese-root, batates, yams, etc., to rot in water, to see whether different organisms result. My observations are, however, as yet in their infancy, as I only learnt the primary fact a few weeks ago.

Before concluding let me warn any private practitioners who might ask your advice, against coming to Natal for practice. There is no opening at present in either of the towns with even a shadow of success; and as for the few scattered settlers in the country, I am sure there is no district where £100 a-year can be made. There are, however, good openings in the Cape Colony for an indefatigable rider; but a man must have an iron constitution, and minister freely to the prejudices of half-savage Boers.

## GENERAL CORRESPONDENCE.

### THE MARSHALL-HALL METHOD OF TREATING APNŒA.

[To the Editor of the Medical Times and Gazette.]

SIR,—I believe Dr. Sylvester to be correct in stating that in the Marshall Hall method of treating Apnœa the capacity of the chest is not increased,—only the supplemental air is acted upon; but I also believe that this air is sufficient, and more than sufficient, to sustain life in the cases requiring its employment; for in the living body the air which may be thus acted upon averages from 75 to 100 cubic inches (four to five times the natural breathing volume); even in the dead body we obtained an average above that of the breathing volume, which is set down by Dr. Hutchinson at 20 cubic inches.

In your Journal of February 6th, Dr. Sylvester endeavoured to demonstrate the superiority of his method to that of Dr. Marshall Hall. It is true, *primâ facie*, that his method appears to have its advantages, and I am not in a position to deny them,—neither have I a wish to do so, if his method be superior; but the experiments which he adduces as proof appear to me quite imperfect; certainly they do not prove what he has asserted in your impression of last week, that "the quantity of air respired according to my experiments on the dead body appears to be ten times greater in my method than in the Postural method." This I believe to be simply impossible: for, taking our average at 30 cubic inches, it would make Dr. Sylvester's average 300 cubic inches, which is far above the average vital capacity of the healthy living chest, as shown by the extensive observations of Dr. Hutchinson.

In our experiments, which extended over a period of from six to nine months, we were enabled in our later trials to account for and avoid many difficulties which at first assailed and puzzled us; and as I think Dr. Sylvester has foundered on the same sands, if you will allow me, I will make a few remarks which I think would assist in making his experiments more definite.

As I understand his letter of February 6, it would appear that in no experiment was there more than from a cubic inch to a cubic inch and a half of air acted upon, only so much as would raise or depress the water in the bent tube; if this were correct it is manifest that neither method, as he employed them, would suffice to give life to the lungs. I think the following the main causes of the difference between his results and ours.

1st. If there be more than just sufficient water to fill the bent part of the tube there is too much resistance for the air to bubble through it. 2nd. The presence of *rigor mortis*; this is most difficult to overcome effectually, because, though after moving the body about for some time the parietes of the chest do relax to a certain extent, the lung tissue never regains the resiliency after *rigor mortis* which it had before; so that in the living, half-drowned body the inspiration in the "Marshall Hall method" would be more satisfactory than in the dead.

As Dr. Sylvester in his last letter acknowledged the necessity of the "management of the tongue," I shall make no further comment upon it. There is, however, another difficulty to be avoided,—the obstruction caused by regurgitated fluids from the stomach in certain positions of the body;—this danger, with the still more formidable one of the paralysed tongue, was overcome by Dr. Sylvester in the easiest possible manner,—by inserting the tube into the trachea below the possible causes of mischief.

If the india-rubber tube were inserted into one nostril, and the mouth and opposite nostril closed by layers of linen smeared with some unctuous substance (plaster will not stick), it would show whether there were any obstruction in various positions. But, here again, care must be taken that the tube is not closed by pressure between the vomer and turbinated bones; also, that the channel is not obstructed by inspissated, mucous, or other matters which often accumulate in the dying. It must be seen, too, that the tongue is lax and in a condition similar to the living, for during the existence of *rigor mortis* the cellular tissue of its substance is much as though it were

frozen, and consequently it would not loll back and point out danger, as when lax. If Dr. Sylvester considers these suggestions worthy of adoption, I think his experiments might be relied on with more justice, and his method even tried when a life is at stake; the experiments would, however, be still better, if he attached an elongated tube of oiled silk, which would contain a known quantity of air, to the free end of the bent tube; he would thus demonstrate the amount of air acted upon in a clear and definite manner.

There are two other points of great importance in Dr. Sylvester's letter, which are totally at variance with our experience. 1st. He says that "the tongue does not offer any serious obstacle to expiration, when that is induced by compression of the thorax." A reference to the detailed experiments in Dr. Marshall Hall's work on "Drowning," will at once show how constantly it happened, that by no amount of compression of the thorax could we succeed in producing expiration when the tongue or fluid obstructed the way.

2ndly. He states that when the body is "placed on the side and a little beyond," the tongue falls back, and effectually closes the glottis. I can only say that I never once met with this difficulty,—neither did Dr. Sylvester himself, if we may judge from the report of his experiments of Feb. 6, in which he states that when the body was placed in this position "the column of fluid fell slowly to its former level," which was his indication that the air which had been previously expelled was again inspired. I am, &c.

"A SECOND COADJUTOR IN THE DISCOVERER'S EXPERIMENTS."

Folkstone, March 20, 1858.

#### APHTHÆ OF CHILDREN.

LETTER FROM J. BRAXTON HICKS, M.D.

[To the Editor of the Medical Times and Gazette.]

SIR,—The aphthous condition of the mouth occurring in children has been frequently described, under the names of stomatitis aphthosa, gingivitis, and aphthæ. Many being the forms and varieties of the disease, according as it occurs in older or younger subjects, in debilitated or robust, in crowded dwellings or in fresh air.

I have not been able to meet with any description of this disease in the form I have observed it in this neighbourhood. It was very prevalent in the autumn of 1857, at which time and since I have had at least thirty cases under my care, all of them presenting the same features, and running nearly the same course.

In all the cases there have been no very severe symptoms, the complaint attacking chiefly children from one and a half to ten years old. The similarity of the whole condition to an exanthem, is the principal reason for my troubling you with this communication.

*Symptoms.*—The first are shivering, headache, succeeded by feverishness, sometimes much heaviness, and sopor accompanied by a very furred tongue, with injected papillæ, and thirst, very like the early days of common continued fever. This state continues for about three days, when aphthæ begin to form on the mucous membrane of the mouth, which increase in size, some becoming as large as a sixpence. In all cases there is, as usual, much tenderness of mouth, spongy bleeding, swollen gums, pytalism, and fetor of breath. These aphthæ continue generally four or five days, and then gradually disappear. The feverishness begins to subside on their appearance, the constitutional disturbance abates, and the appetite returns before the soreness of the mouth, which prevents the little sufferer from eating anything solid, has subsided. The bowels are, as far as I have noticed, not affected through its whole course by diarrhœa; indeed, they have been generally confined. The usual duration of this condition is three days before the aphthæ, and four to seven days after, making nine or ten days its average duration.

In many cases occurring in families it has passed through the whole children in succession, very much as measles and scarlatina are wont to do. In this case there has been about eight or ten days between the separate attacks.

The patient is generally left languid, pale, and weak; but this state soon passes away with the assistance of tonics and good diet.

The treatment I have found most efficacious is chlorate of potass dissolved in water, so as not to be too pungent for the mouth, three times a-day, with a gentle purge of hydrarg. c. cretâ. The mouth cleans rapidly on its use, and the fetor of breath is much improved directly it is used. I have thought it useless to trouble you with detailed cases; they are so much alike that the above description will answer for all.

Those violent epidemics of gangrenous ulceration of the cheek and gums, which are seen in large pauper juvenile establishments, appear to have features not dissimilar to the above, differing of course in severity, a description of which, by Dr. Duncan, may be found in the *Dublin Journal*, Sept. 1846, where there was about three days fever previous to the ulceration of mouth, and death seemed to take place rather from the high fever and diarrhœa than from any changes effected in the condition of the mouth. The ages of the children varied from 1½ to 5 years, and in some cases more than one member of the family was attacked. I am, &c.

J. BRAXTON HICKS, M.D. Lond. &c.

Tottenham, Middlesex.

#### DIPHTHERIA.

LETTER FROM DR. HESLOP.

[To the Editor of the Medical Times and Gazette.]

SIR,—Since the date of the last paper published in your Journal, I have had three cases of the disease in the Queen's Hospital. One, very severe in a young man, secondary to scarlatina; another, of moderate severity, in one of the nurses; the third, very mild, and treated on the day of its appearance, in a young servant of the Institution and daughter of the second case. All these patients were treated successfully on the plan laid down. It is important to mention that erysipelas has been unusually rife in the town during the last few weeks, and has attacked the Hospital patients with a violence hitherto unexperienced. Ten days ago I saw a rapidly fatal case, with Mr. Sproston, of malignant pustule on the face.

But one of the most severe illustrations of the malady which have yet occurred to me, fell under my notice last Tuesday, the 11th. It is a representative case, equally in reference to the majority of the symptoms and to the effects of the treatment. On that day I was sent for at 3 o'clock in the afternoon, by my colleague, Mr. Langston Parker, to see a girl, A. H., aged 10, living at Ashted. That gentleman informed me that he had been in attendance four or five days; that, the night previously, he had advised a consultation, which was not agreed to; but that on seeing her deplorable condition early in the morning, he had obtained the assent of the friends to that measure, but he thought all consultation unpromising, as her state appeared now almost to preclude hope.

The patient has a dark complexion, eyes, and hair; parents cousins; several children have died of various infantile disorders. The family are eminently weakly. The mother informed me that for two or three weeks the girl had been out of health, and especially had been troubled with diarrhœa. About five days before my visit she complained of sore-throat, and there was marked swelling under the jaws, with feverishness, anorexia, and loss of sleep. Mr. Parker observed that there was swelling of the tonsils, and a general cedematous rubescence of the palate and posterior fauces, but did not note exudation anywhere. The symptoms daily became aggravated, and on Sunday, the 9th, dyspnœa to an extreme degree was superadded to the symptoms, the stridor being so loud and whistling as to be distinctly heard in the garden. These symptoms, conjoined with delirium, great restlessness, and prostration, assumed the most formidable proportions the next day—that preceding my visit. The usual remedies had been sedulously employed, such as caustic solutions to the fauces, etc. Several blisters had been applied to the throat, just beneath the jaw, which seemed to give relief.

I found her very restless; face pale, and indicative of prostration; eyes languid, and deeply sunken; delirium constant; complete insomnia. A thin sero-purulent discharge constantly trickled from the nares, the upper lip excoriated. Breathing stridulous, and accompanied by nasal sounds. This symptom seemed to Mr. Parker less severe than in the early part of the morning. A most complete aphonia. Dys-

phagia inappreciable. Fluids had never returned through the nose. Skin dry and harsh, not markedly above the ordinary temperature. On the uvula, tonsils, and velum were scattered patches of slightly yellowish exudation, especially on the edges of the uvula. These parts were swelled, and highly congested, but not of a violaceous tint. I could not observe any ulceration. The lips and general buccal membrane free from deposit. No hæmorrhages or petechiæ existed. Bowels once moved this morning. The blistered surfaces were covered with a fibrinous film, and looked "angry."

We agreed that we had to contend with a most formidable case of epidemic angina membranacea, and resolved upon the use of the dilute hydrochloric acid to the affected parts (of the fauces), which was thoroughly effected several times by Mr. Parker. Weaker gargles of the same acid were ordered; wine and beef-tea at frequent intervals; eggs and milk, as far as they could be pushed. A mustard emetic was directed to be administered immediately, and the following medicine every second hour, in table-spoonful doses:—*R. Acidi hydrochlorici dil. ʒss. ; tinct. ferri sesquichloridi, ʒjss. ; syrupi aurantii, ʒss. ; aquæ, ʒv. misce.*

In the evening Mr. Parker saw her, found that two mustard emetics had failed to operate, and that the medicine had not been administered; but the stimulants, etc., had been proceeded with. He thought the patient rather better, and reapplied the acid.

12th.—There is a striking improvement in her condition. Several hours' sleep had been obtained, though delirium still existed. The countenance is better; exudation less marked on the fauces, though in considerable quantity. The breathing much easier; stridor scarcely observable, but aphonia hardly less complete than before. Pulse weak, but firmer than yesterday, about 100°. Bowels not moved once. The medicine has been given pretty regularly since 8 o'clock last night. The vesicated surfaces less coated, perhaps, than yesterday. The acid was again freely applied, and everything else ordered to be persisted in.

13th.—Breathes and swallows easily; stridor has disappeared; slept eight hours in the night; eyes bright; expression animated; a little colour in the cheeks. Skin moist; pulse less frequent and stronger; tongue moist. Exudation still exists on the fauces, but is greatly diminished. Nares do not pour out so much ichorous fluid. She wants to get up. The blistered surfaces look healthy, and the fibrinous film has all but disappeared. Bowels not open for two days. Peristaltic action immediately. Yeast and water to be syringed frequently into the nares and mouth. The recumbent posture strictly enjoined.

Mr. Parker informed me on the 15th that she was fully convalescent, and had eaten a mutton chop the night before, against orders; but there was an increase of the discharge from the nares. On the 16th he writes me: "Miss H. continues better. She is to-day up and dressed, and none the worse for it. Tongue clean; appetite good; bowels acted; pulse 74. No remains of throat mischief except a very slight white streak down the uvula. Discharge from the nose again much diminished." I am, &c.,

T. P. HESLOR.

#### INSTRUMENT FOR EXTRACTING BODIES FROM THE ŒSOPHAGUS.

LETTER FROM MR. JOHN ADAMS.

[To the Editor of the Medical Times and Gazette.]

SIR,—A few years ago I published in your journal a lecture on some cases of foreign bodies in the œsophagus, and made particular allusion to the propriety of extracting them rather than forcing them into the stomach by the probang. In a late number of the *Medical Times and Gazette* I find recorded a fatal case, in which a gentleman had, during sleep, swallowed some false teeth with the gold plate attached. They were arrested low down in the œsophagus, and the Surgeon forced them into the stomach with a probang. I do not make any especial allusion to the treatment pursued in this instance, as I dare say everything was done which could be accomplished for this gentleman's relief; but I am quite certain that in all cases of foreign bodies in the œsophagus, it is far better to get them up than to force them down; and I feel satisfied

that the extraction of foreign bodies can be accomplished with much greater facility than is commonly supposed if the proper means are had recourse to.

The employment of properly constructed forceps first suggests itself to us; and, failing in the use of this instrument, there is another which is so simple and efficacious that I cannot help alluding to it again as a means of extracting foreign bodies, however low they may have descended into the œsophagus.

The instrument is not new, but it is not in general use. It consists of a button-like hook placed at an angle of about 35°, and attached to a steel spring, which is fixed to the end of an ordinary probang. I send you a copy of one I am in the habit of using.

Its employment is quite unattended with risk, and by its means it is possible to remove foreign bodies, especially those with rough and irregular edges, however near the stomach. You will excuse my mentioning the subject again. I am, &c.

JOHN ADAMS.

4, St. Helen's-place, May, 1858.

#### ON THE USE OF TANNIC ACID IN NÆVI.

LETTER FROM MR. HAYNES WALTON.

[To the Editor of the Medical Times and Gazette.]

SIR,—I am frequently receiving notes of inquiry respecting my method of using tannic acid in nævi, and shall be obliged by your allowing me to give publicity, through your journal, to those matters on which I am generally questioned.

My paper containing my first trials with the acid, and which was read at the Medico-Chirurgical Society, is published in the second volume of the *Proceedings*, page 27. "H. Walton on a vascular tumour in the orbit, successfully treated by tannic acid."

The strength of the solution is in the proportion of a drachm of the acid to an ounce of water. This amount of water will dissolve more than two drachms of acid; but I should not like to employ so strong a preparation; I think therefore that a saturated solution is objectionable.

I do not consider that my plan is preferable to all others, but suitable and superior in the cystic and the subcutaneous varieties of nævi. Further investigation may induce me to extend it to other instances, but I still tie and cauterise some of the superficial forms of the disease.

My method of proceeding is this:—I make an aperture at the circumference of the tumour, with a knife that will not make a larger hole than the nozzle of the syringe requires. I have always used one of my smallest sized iris knives. Sometimes when I think it beneficial, this depending on the greater density of the mass, I move the needle about, so as moderately to cut the interior in several places, that the injection may traverse sufficiently freely.

My syringe is a metal one, holds about an ounce, and has a long and fine point. Mr. Fergusson, the surgical instrument maker of Giltspur-street, Smithfield, has made several of the kind.

When practicable, I think it well to empty the nævus by pressure before injecting, and then gently to distend it. All force is improper, as it risks extravasation. Commonly a few days after operating a darkish coloured discharge issues from the point of puncture. Less frequently nothing of the sort ensues, but the coagulated blood is gradually absorbed.

I am, &c.,

H. HAYNES WALTON,

Surgeon to St. Mary's, and to the Central London Ophthalmic Hospitals.

June 4, 1858. 69, Brook-st., Hanover-sq., W.

## REPORTS OF SOCIETIES.

## ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MAY 25, 1858.

Sir C. Locock, Bart. President, in the chair.

Mr. Tudor read a paper on

## CASE OF EXCISION OF THE ELBOW-JOINT, IN WHICH A CONSIDERABLE LENGTH OF BONE WAS REMOVED.

The patient was a Lascar seaman, a native of Bengal, aged 24, who was admitted into the Hospital, July 31, 1857; the left elbow-joint being completely destroyed, and surrounded with pus, while motion was attended with a distinct rough grating sensation: the general condition of the man being unfavourable. His health having improved very much, resection of the joint was performed in the following manner, on the 26th of August:—A longitudinal cut being made on the inner side parallel with the ulnar nerve, and carried to about four inches in length, was joined by a second incision extending transversely across the back of the joint from one condyle to the other; the olecranon being removed by the bone forceps, so extensive an amount of disease of the humerus was revealed, as to necessitate the prolongation of the longitudinal incision to the extent of a further  $1\frac{1}{2}$  inch, and the removal of fully 3 inches of the lower extremity of the bone. The head of the radius was then excised within its capsular ligament, with about three-quarters of an inch more of the ulna. The case progressed favourably. The man was exhibited to the Society at its meeting on May 11, when the arm was found to have regained considerable strength, so much, indeed, that underhanded, he could lift a heavy chain, and carry a bucket: when allowed to hang loosely by the side, the interval between the extremities of the bones did not appear to exceed half-an-inch; but when flexed they were brought into close approximation; and it could be felt that the humerus was much expanded, so as in a great measure to compensate for the natural condyloid extremity as a base of support, while a corresponding osseous growth on the ulna might be regarded as representing the olecranon. It was thus proved that at least five inches of bone might be removed in excision of the elbow-joint, and, nevertheless, an efficient member retained, with an articulation capable of useful and extensive motion. The portions of bone removed were exhibited to the Society. Mr. Spencer Smith exhibited to the Society the portions of bone removed from the elbow-joint of a man in the Middlesex Hospital by Mr. De Morgan, which in curiously minute particulars most closely resembled those in Mr. Tudor's case, save that the portion of the ulna was not quite so large. The case was going on equally well, but the operation having been performed on the 10th of December only, and the patient having had to contend with the healing of a large pectoral abscess, the pulse-joint was not yet equally strong as in Mr. Tudor's case.

Mr. SKEY said, that in no joint in the body was the operation of excision more apposite or more successful than in the elbow. The number of cases had been very large, and the amount of success had been proportionately great; but he thought that in the present day, when there was so great a leaning in favour of resection or excision, it would be well that the rules of management as regards the operative proceeding, should be more clearly defined than they were. He observed in the specimen exhibited a necrosed portion of bone occupying the shaft of the humerus above. There could be no doubt that any operation of excision of the elbow-joint must be imperfect that did not remove the sequestrum or necrosed piece of bone; but he should like to ask the author whether, before the extensive disease for which he performed the operation, there was any evidence which marked it as a case of necrosis rather than disease of the joint itself, and whether it was necessary that portions of the radius and ulna should be extensively removed. The highest authority upon the subject of resection of joints was present (Mr. Fergusson), and he should like to ask him how far, especially

in the case of the elbow-joint, it was necessary to remove the articular surface of the bones of the forearm, or whether, as a general rule, he would not be content to leave those bones, and to remove only the portions of the humerus that were the seats of disease.

Mr. FERGUSSON thought it extremely probable that the disease of the elbow-joint in the case in question might have been secondary,—that there might have been first necrosis of the lower end of the humerus, and that the inflammation resulting therefrom had extended to the joint, and caused one of those formidable joint diseases which were so long in getting well spontaneously. He believed the author had acted with judgment in removing the necrosis, seeing that nature had shown no effort towards its removal; and in regard to his mode of dealing with the radius and ulna, he had also acted in accordance with all that was at present known upon the subject. He was not prepared to give a positive opinion upon the point, but as far as his own experience went, he was disposed to think that it was not doing justice to the patient to take away only half of a joint in resection, and that it was better that the opposing articulating surface should be removed at the same time. He believed there was little yet remaining to be known as to the operative procedure in regard to resection, especially of the elbow-joint, the operation having been performed so frequently. Of course, the Surgeon should have the option of modifying his incision at will. He did not think it wise to lay down any exact form, but thought the Surgeon should be allowed to exercise his judgment as to the best forms in any given case. He considered the case related by the author to be an admirable illustration of the advantages resulting from the operation. He did not believe with many that amputation was the opprobrium or disgrace of surgery; but he desired that it should be avoided as far as possible, and believed that in very many instances resection might be adopted in its stead.

Mr. SKEY, while giving credit to Mr. Fergusson for re-introducing, after an interval of twenty years, one of the most important operations in surgery, thought that great care should be taken to employ every other available means before having recourse to that method. He was not prepared to allow that all the skill of curative surgery had been employed upon many of the cases in which the operation had been performed.

Mr. TUDOR said, that when he commenced the operation he did not expect that it would be necessary to proceed so far, but he deemed it much safer to remove the bone to the extent he had done, than to allow any to remain to which there was attached the slightest suspicion of disease. Whether or not the bones he had removed would have recovered, the operation showed what result might be expected when there was no question as to propriety of removing bone to that extent.

Mr. WILLIAM COULSON then read a paper on a case of

## HYDATIDS OF THE TIBIA.

The patient, a female, aged 25, was admitted into St. Mary's October 20, 1857, with a swelling of the size of an orange in the front of the right leg, just below the tuberosity of the tibia: in the centre of the swelling there was a small ulcer, and the surrounding integuments were red and swollen. The discharge, which was not considerable, was found to contain accephalocysts. It appeared from her history, that eight years previously the patient had received a kick on the front of the right tibia, a little below the insertion of the ligamentum patellæ, which injury was soon followed by a swelling which increased in a gradual and steady manner until it attained the size of a hen's egg. Slight pain attended the growth, but no great inconvenience until four years ago, when the pain becoming severe, the tumour was frequently blistered with relief, but the swelling remained in much the same condition until the beginning of August last, at which time it first gave way, spontaneously, and matter containing accephalocysts was discharged. The anterior wall of the tumour, containing a large hydatid about to escape, was removed with the saw and bone forceps, and a cavity exposed, which extended within half an inch of the knee-joint, and two inches or more down the shaft, and from which a considerable number of hydatids were removed. The whole of the cavity was lined by a white glistening membrane. After removal of all the hydatids to be found, Mr. Coulson rubbed the lining

membrane of the cavity freely with solid nitrate of silver, and filled it with cotton wool. The woman was discharged on February 6, with the wound nearly healed.

Mr. SKEY agreed with the author as to the difficulty of diagnosing diseases of bone, especially of the tibia. He remembered a case in his own practice somewhat analogous to that mentioned by the author in its external characteristics, but differing in its issue. The patient, a child, had a considerable swelling of the upper end, near the head of the tibia. For seven years it gradually increased until it assumed an enormous magnitude; but the movement of the knee-joint—a joint about which there seemed to be something sacred in the eyes of nature—remained perfect. With the concurrence of Sir Benj. Brodie, he laid open the cavity, which contained more than a pint of enchondromatous matter. The walls of the tibia were as thin as a sheet of paper. On the removal of the matter, the cavity was filled with lint. It was about eighteen months before the limb was restored; the walls had fallen in, and the bone became solidified. The operation was performed 2½ years ago, and in another year or two the patient (now about 17 years old) would, no doubt, have a useful limb.

Mr. OBRÉ said he saw the case related by the author, and confirmed his description. It was at first supposed that there were no echino-cocci present, but they were afterwards distinctly observed.

(To be continued.)

## THE PATHOLOGICAL SOCIETY.

TUESDAY, MAY 18.

DR. WATSON, President, in the Chair.

MR. BRYANT showed a specimen of

### MEDULLARY AND CYSTIC DISEASE OF THE TESTIS.

It had been taken from a man aged 26, who was admitted into Guy's Hospital upon April 17, under the care of Mr. Cock. He had a pale and cachectic appearance, and had experienced but indifferent health. From boyhood, after retaining his urine for some time, his right testicle retracted and disappeared from the scrotum, causing at times great pain. Six years ago he had gonorrhœa, and one year ago a chancre upon his penis, but unattended with any secondary symptoms. About one year since, without any blow or known cause, his right testis began to enlarge, unattended with any pain: since that time it has gradually increased, and upon admission it was about four inches in its longest diameter; it was quite painless, and could be manipulated without inconvenience, and squeezed without causing its peculiar sensation. It was of an oval shape, slightly flattened, and in points gave a fluctuating sensation. It was explored with a needle, and only a little bloody serum came away. The inguinal glands were slightly enlarged; and with the exception of having lost flesh for the last three years, he was comparatively well, although for the last year he had experienced flying pains down the right leg, at times very severe. Upon April 20, it was excised, and upon examination the disease was evidently connected with the body of the testis, which was smooth, firm, and in parts distinctly fluctuating. The epididymis was much wasted, and beneath its serous covering were developed cysts of different sizes, and from the caput major two may be seen attached to the body by long peduncles, one being nearly an inch long. The few I opened contained clear serum, and no spermatozoa. Upon making a section of the tumour, all signs of the body of the testis had disappeared, the disease having apparently been developed in it: it was composed entirely of cysts of different sizes (varying from that of a walnut to a millet-seed), some containing others of a smaller growth, and these again containing a third series; some were filled with a clear serum, and others with a bloody or tenacious fluid; and some were filled with a soft pulpy growth, composed entirely of nuclei and nucleated cells, and indeed presented all the appearances of the medullary cancer. From the above examination there can be no doubt that the specimen is a mixed one of the cystic disease and the medullary cancer; it seems to have been developed in the body of the testis, as well as in the rete-

testis, the reputed general seat of the cystic disease; and the simple cysts developed in the epididymis, and upon it, are apparently examples of the more simple form of cysts as found upon the testis. Upon the whole it would appear, that the true cystic degeneration was the chief disease, and that the medullary disease was grafted upon it. The specimen is a good one, illustrating the development of simple cysts which at times form the encysted hydrocele, the true cystic disease of the testis, and the medullary.

Dr. WILKS showed

### SPECIMENS ILLUSTRATING SYPHILITIC DISEASE OF THE LIVER.

He stated the difficulty which existed in the attempt to prove positively the connexion between syphilis and organic changes in the internal organs of the body, and he also alluded to the different opinions on the subject. He, himself, had no doubt of the effects resulting from syphilis, and that in the cases of fatal cachexia following it, various visceral changes would be found. He had no doubt of syphilitic pulmonary affections nor of disease of the blood-vessels, exhibited more especially in those cases of paralysis associated with the tertiary forms of the complaint, and due to a softening of the cerebral structures. With respect to the liver, the disease was manifested by the production of fibroid nodules, as seen in the Plate in the last volume of the Society's Transactions. The true specimens now exhibited showed similar fibroid deposits scattered throughout the organ, and in one case there was associated with them a waxy or lardaceous disease, a condition very frequently found in those who have died of syphilitic affection of the bone. The first case was that of a man who had been invalided for six years on account of various syphilitic ailments, as nodes on the bones, rheumatic pains, cutaneous eruptions, etc. He died with a waxy spleen and liver, and throughout the latter there were nodules of a fibroid deposit. He had been intemperate, and the only doubt was, how far the fibroid condition was allied to ordinary cirrhosis and due to alcohol; but inasmuch as the waxy change, without doubt, was an important part of the general cachexia, there was an equal probability in favour of the other condition being also a part of it. In the second case there was necrosis of the clavicle, scars on the body denoting an old ecchymatous eruption, a waxy condition of kidney and spleen.

Mr. CHRISTOPHER HEATH exhibited

### AN EDENTULOUS LOWER JAW WITHOUT MENTAL FORAMINA.

The specimen was taken from a subject above 90 years of age, during the dissection of which no trace of the inferior dental nerve on the face could be found, and upon maceration the mental foramina were found entirely obliterated. Mr. Heath considered the specimen of interest as bearing on a portion of necrosed lower jaw, removed, and exhibited by Mr. Bryant, in which both mental foramina were included without any diminution of sensation in the chin. In the present instance no nervous supply to the chin could be detected.

Dr. GIBBON showed a specimen of

### SCIRRHUS OF THE OMENTUM.

The specimen was of interest as showing a rare form of cancer of the omentum. There was some uncertainty as to the primary seat of the disease, but Dr. Gibbon was led to assign it to the omentum, on account of the long duration (eighteen months) of the tumour, and from the fact that the outer coats of the gut were more affected than the inner, the mucous membrane on the annular constriction being only partially removed. The diagnosis both as to the seat and nature of the obstruction was accurately made out, and the operation was skilfully performed by Mr. Borlase Childs, but the patient sank a few hours after the operation. For three days previously she had declined operative interference, and consequently was in a very exhausted state at the time of operation.

**DEATH FROM CHLOROFORM.**—A patient, under the care of M. Ceccaldi, at the Gros-Caillou Military Hospital, who was about to submit to an operation for the removal of a testicle, and to whom chloroform was administered, died before the operation was commenced.

## HARVEIAN SOCIETY OF LONDON.

THURSDAY, MAY 6, 1858.

DR. HAMILTON ROE, President, in the Chair.

## CASE IN WHICH THE OPERATION OF PARACENTESIS THORACIS WAS PERFORMED FOR THE RELIEF OF OBSTINATE VOMITING.

The particulars of this case, communicated to the Society through Dr. Hamilton Roe, the President, by Dr. Heslop, of Birmingham, were as follows:—The patient was a girl, aged 20, who had been for two months affected with effusion into the left pleural cavity. Extreme emaciation, night sweats, etc., were present; but in addition to these, no food of any kind was retained by the stomach. No relief following ordinary measures, and it being evident that the patient was dying of inanition, Dr. Heslop advised the performance of the operation. Two pints of fluid were drawn off, and the relief which followed was immediate and complete. The patient rapidly recovered. Dr. Heslop added, that in advising the performance of the operation, he took the same general line of argument as that pursued by the accoucheur in inducing artificially premature labour, when the interference with important functions as that of the stomach, calls for that proceeding.

The PRESIDENT then related the particulars of a case of circumscribed empyema occupying the left mammary region in a child aged 9. The diagnosis having been fully established, a canula and trochar were introduced, and ten ounces of a puriform fluid drawn off.

Mr. WREDDEN COOKE read a paper on

## SCROFULOUS DISEASE OF THE TESTICLE,

the principal object of which was to show the advantage of constitutional treatment, by means of which castration might be avoided. He described the causes and nature of this disease; for the purposes of diagnosis contrasted it with the other lesions of this gland, viz. scirrhus, cephaloma, cystic disease, syphilitic sarcoma, and common hypertrophy; and related several cases in which there had been tubercular enlargement with abscesses, and in some a protruding fungoid growth. In all these cases he had found a combination of iron in full doses, with iodide of potassium, so improve the vital powers that, with the aid of a sulphate of copper lotion, or the salt itself applied to the ulcers, a perfect cure was obtained; whereas it frequently happened that after the removal of a tuberculous testis by the knife the disease would reappear in the remaining one.

In the discussion which followed, Dr. Camps, Dr. Handfield Jones, Mr. Ballard, Mr. Stewart, and Dr. Coote joined.

Mr. Cooke having replied, the Society adjourned.

## WESTERN MEDICAL AND SURGICAL SOCIETY.

May 7, 1858.

THE Annual meeting took place this evening, and after the Reports of the Council and Auditors had been read, the following officers were elected for the ensuing session, 1858-59.

President.—A. B. Barnes, Esq.

Vice-Presidents.—Dr. Fuller, Mr. Martyn, Mr. Keen, Dr. Fincham.

Council.—Dr. Barclay, Dr. Traquair, Dr. W. Ogle, Mr. Taylor, Mr. James Lane, Dr. Aldis, Mr. Hatfield, Mr. T. Dickinson, Mr. Henry Brown, Mr. Turner, Mr. Mould, Dr. Cahill.

Treasurer.—Dr. Seaton.

Hon. Secretaries.—Dr. Baines, Mr. Milner.

Hon. Librarian.—Mr. Cumberbatch.

Auditors.—Dr. C. G. Brown, Dr. Stackpoole.

The PRESIDENT then addressed the meeting, and after returning thanks for the complimentary resolutions to the officers for their services during the past year, made some remarks on the subject of ovariotomy. He had been led to this subject by a case in which he had lately operated, and

which was now progressing to a favourable termination. The patient was 19 years of age; the disease a large unilocular ovarian cyst, containing four gallons of fluid; there were no adhesions. Having given the details of this case he adverted to his individual experience of operative proceeding for the radical cure of ovarian dropsy which extended over 13 cases. In 8 of these (including the one alluded to) the cyst was removed from the abdominal cavity; in the remaining five the tumour, on account of adhesions, could not be removed. Of the 8 removed 2 of the patients died from the immediate effects of the operation, and 6 recovered, showing a mortality of 1 in 4, or of 25 per cent. Of the 5 cases in which the tumour could not be removed, all recovered from the operation; thus in the 13 cases the mortality was only 2, or 1 in 6½. He need hardly say that, as compared with other capital operations, this was a small per centage of deaths; for instance, in amputations of all kinds, excepting fingers and toes, the mortality was 1 in 3, in the thigh it was 1 in 2½, and in the leg 1 in 3, in the arm 1 in 3½. In hernia the deaths were as 1 to 2½, in ligature of the subclavian the mortality was 1 in 2, of the common iliac, 1 in 2½, of the internal iliac, 1 in 2½, of the external iliac, 1 in 4½, of the carotid, 1 in 4½. In lithotomy in the adult the mortality was from 1 in 5 to 1 in 2, depending upon the age of the patient and the size of the stone. Dr. R. Lee's cases of ovariotomy, published in *Medico-Chirurgical Transactions*, 1851, were the most unfavourable. Out of 162 cases, 60 could not be removed; in five of these no tumour was present; of the 60 cases 19 proved fatal, or rather less than 1 in 3. In the remaining 102 the disease was removed; in one of these cases both ovaries and the uterus were excised, and in another the ovary, with part of the uterus, and in two cases both ovaries. Of these 102 cases 42 proved fatal, or about 1 in 2½. Dr. Clay, of Manchester, had had more experience. In a paper read by him, in August last, in Edinburgh, he stated that he had operated in 79 cases, and that 55 had proved successful, the mortality being about 30 per cent., or less than 1 in 3, and expressed the opinion that the mortality in future would not be more than 1 in 4; and that the existence of adhesions, as far as his experience went, did not interfere with the successful result. In these opinions the President coincided. Dr. Atlee, of Philadelphia, had operated on 36 cases, 12 of which were fatal, or 1 in 3. In 13 cases where the cyst was removed, occurring in the practice of Dr. F. Bird, 4 were fatal, or rather less than 1 in 3. In 21 cases, recorded in Ranking's Abstract and Braithwaite's Retrospect, since the date of Dr. Lee's paper, 7 proved fatal, or 1 in 3. Hence he believed that we were not only warranted in performing the operation in properly selected cases, but that it was our bounden duty to recommend it. For the last twenty years this operation had been submitted to the Profession through the press and Medical Societies, and the rate of mortality, he maintained, had been established at about 1 in 3. It had been said that the favourable cases only had been published, and that the statistics could not be depended on. He believed, however, that all the cases operated on during the last twenty years had been more carefully watched, and made known by the operation and others, than had any cases of other operations of Surgery. If these cases were considered in the mass, he would ask, why should not 200 sufferers from ovarian dropsy be saved out of every 300 operated on? you did not hesitate to save 200 out of other 300 cases of Surgical operations, where the rate of mortality was similar. At any rate, he for one did not hesitate to express his opinion, that the time had now arrived when the Profession would be wanting in their aid to the sufferers from this distressing, and ultimately fatal disease, if they withheld from them any longer the benefits to be derived from the performance of the operation.

The business of the Session then terminated by the usual *conversazione*.

## ST. MARY'S HOSPITAL MEDICAL SCHOOL.

On Saturday afternoon the distribution of Prizes and Certificates of Honour awarded to the Students during the past year in this School took place in the theatre of the Hospital at Paddington, under the presidency of the Right Hon. Sir James Stephens, K.C.B. LL.D., the Regius Professor of

Modern History in the University of Cambridge. The Medical officers and lecturers were present during the proceedings, which were graced by the attendance of a numerous assemblage of ladies, friends of the students.

The Prizes and Certificates of Honour were distributed in the following order:—

Anatomy, Senior, 1867-58—Prize: Mr. Arthur Myers. Certificate of honour: Mr. Henry Ubsdell.

Anatomy, Junior, 1867-58—Prize: Mr. Alfred J. Belemore.

Certificate of honour: Mr. Arthur B. Brown and Mr. Frederick J. Rogers—equal.

Chemistry, Junior, 1867-58—Prize: Mr. Alfred J. Belemore.

Medicine, 1867-58 — Prize: Mr. James Henry Jeffcoat.

Certificate of honour: Mr. Stamford Felce.

Surgery, 1867-58—Prize: Mr. Thomas L. Ash. Certificate of honour: Mr. James Henry Jeffcoat and Mr. H. Howard Hayward.

Clinical Medicine, 1867-58—Prize: Mr. Thomas L. Ash.

Clinical Surgery, 1867-58—Prize: Mr. Stamford Felce.

Military Surgery, 1866-57—Prize: Mr. H. Howard Hayward.

Certificate of honour: Mr. Dracachis.

Botany, 1866-57—Prize: Mr. James E. Trevor. Certificate of honour: Mr. Henry Ubsdell.

Materia Medica, 1866-57—Prize: Mr. Stamford Felce.

Certificate of honour: Mr. Henry Ubsdell.

Midwifery, Senior, 1866-57—Prize: Mr. Henry Ubsdell.

Certificate of honour: Mr. Thomas L. Ash and Mr. H. Howard Hayward.

Midwifery, Junior, 1866-57—Prize: Mr. Stamford Felce.

Certificate of honour: Mr. Arthur Myers and Mr. James J. Grosjean.

Practical Chemistry, 1866-57—Prize: Mr. Benjamin Cocks.

Certificate of honour: Mr. Thomas L. Ash.

Medical Jurisprudence, 1866-57 — Prize: Mr. Benjamin Cocks. Certificate of honour: Mr. Thomas L. Ash.

Comparative Anatomy, 1866-57—Prize: Mr. Stamford Felce. Certificate of honour: Mr. Edwin Chisholm, Mr. Henry Ubsdell, Mr. Trevor—equal.

Natural Philosophy, 1866-57—Certificate of honour: Mr. Dracachis.

The Dean's Prize for General Proficiency, 1867-58—Prize: Mr. James Henry Jeffcoat.

The Right Hon. CHAIRMAN then delivered a most able and eloquent address to the students, pointing out the vast importance of the duties which would devolve upon them in the station in life for which they were studying, and giving them some sound practical advice as to their conduct during their studies, and also when practising in their Profession in after-life, urging them to form for themselves some immutable convictions and opinions, without which there would be no stability in progress, and without progress they invariably went back; also warning them that, unless they were gentlemanly in their deportment they would be utterly unfit for their Profession: and further advising them to pay the greatest attention to Medical elocution, for on the mode of addressing those who came under their care much depended. The learned professor was loudly applauded at the conclusion of his address.

A vote of thanks was passed to the Chairman for presiding and delivering his address; and a similar compliment was paid to Mr. Spencer Smith, the Dean, for the great interest he takes in the Institution.

## PARLIAMENTARY INTELLIGENCE.

### HOUSE OF LORDS, JUNE 4.

#### SALE OF POISONS BILL.

The Earl of DERBY, in moving the second reading of this bill, said, its purport and aim were to carry into effect that which had been an object with that and the other House of Parliament for a considerable time, and in reference to which their Lordships last year appointed a select committee, which went very carefully into a consideration of the whole question. The bill was founded almost entirely on the recommendations of that committee. He had referred the measure to the Pharmaceutical Society, and also to the College of Physicians for any observations they might wish to make

upon it, and where those two learned bodies had agreed he had adopted the amendments they had proposed; where they differed he had adhered to the original draught of the bill. The first object of the bill was to increase the difficulty of obtaining poisons for criminal purposes; and the other objects of it were to prevent, as far as possible, the occurrence of those lamentable accidents which arose partly from ignorance and partly from carelessness on the part of those persons who exercised the business of selling drugs and poisons. It provided, among other things, that poisons should not be sold except to persons of full age, who should be known to the person selling them, and whose name should be signed in a book. If the purchaser were not known to the person selling the poison, it was provided that he should produce a certificate signed by a householder, with his name and residence, stating that he knew the person to whom the sale was to be made, and those circumstances were to be entered in a book by the party selling the poison. Those very stringent provisions were applied to a considerable number of poisonous substances enumerated in a schedule attached to the Bill. There were, no doubt, other substances equally poisonous, but, at the same time, the sale of which could not be subjected to all the stringent provisions contained in that first clause, without, in point of fact, altogether destroying certain branches of trade, and preventing the transaction of legitimate business. These were laudanum, opium, tartar-emetic, and chloroform; but it was obvious that there should be some restriction even with regard to the sale of those substances, with the view to the prevention of accidents arising from ignorance, incompetence, and carelessness. It would be recollected that there was conclusive evidence given before the committee of last year that the sale of poisons was carried on by persons who had not the slightest knowledge of the properties of those poisons, and who were utterly unfit by their education and knowledge to deal with such dangerous materials. (Hear, hear.) It was proposed that, preserving to all persons at present engaged in the sale of poisons the right to continue their business, for the future no person should be permitted to sell poisons of either of the classes he had mentioned without possessing a licence, which licence would only be granted after an examination of the party by properly qualified examiners. It was intended that those examiners should be three in number, — one to be appointed by the Pharmaceutical Society, another by the College of Physicians, and the third by the Society of Apothecaries. All those persons who for the space of one year prior to the passing of the Act should have been engaged in the sale of poisons, to be licensed to carry on their business for a period of five years, but the licence would not be continued or renewed at the expiration of that time unless the party submitted himself to an examination. The other question to be considered was that of carelessness on the part of the sellers, and with a view to meet that it was proposed that all persons selling poisons should be required to keep them distinct and separate from all other drugs, and that the examiners or persons appointed by them should be at liberty at all reasonable times to visit all shops where poisons were sold, in order to ascertain whether the requirements of the Bill were complied with. There were pecuniary penalties for infringement of any of these provisions, and it had been considered also lately necessary that when the poison had been improperly sold, or otherwise dealt with by any servant or shopman, the employer should be held liable and subject to the penalties attaching to the offence. With regard to arsenic there was a special provision that it should be kept mixed either with soot or indigo, except in cases where it could be shown that it was required for purposes for which such mixture would render it useless. Those were the main provisions of the Bill; and although some persons were inclined to urge more stringent regulations, yet it had been deemed most prudent to act in accordance with the views of the Medical Profession, and thus insure that willing co operation that was needed to carry the measure into beneficial operation. There were some verbal amendments which would be introduced, and he now proposed to read the Bill a second time, and to go into committee *pro forma* on Monday next.

Earl GRANVILLE thought the Government had acted wisely in adopting the suggestions of the Pharmaceutical Society and the College of Physicians. With regard to the examiners he was not sure that the Government ought not to appoint them, or at least one of them. The Bill, with a few amend-

ments, would, he thought, prove a beneficial measure, and he therefore supported the second reading.

Lord CAMPBELL expressed his entire satisfaction at the prospect they now had of putting an end to the present unsatisfactory state of things as regarded the sale of poisons; for hitherto it was quite as easy to obtain arsenic as snuff or tobacco. This bill was the result of a most laudable and painful inquiry, and he believed that all ranks of society would be most anxious to see the provisions of this bill carried into effect.

The Earl of HARDWICKE said the enormous demands for these articles, especially for opium, went on to such an extent that it was almost impossible to apply a remedy; and it was only last year he received a communication from Manchester, while the bill regulating the sale of opium was under discussion, stating that, if it was passed, the best thing that could be done would be to send a number of strait waistcoats to Manchester, which would most undoubtedly be required if laudanum could not be obtained, so soothing were its effects upon those who had been addicted to its use.

After a few words from Lord Cranworth and Lord Aveland, the bill was read a second time.

### HOUSE OF COMMONS.

#### REGISTRATION OF BIRTHS, MARRIAGES, AND DEATHS IN IRELAND.

Mr. GREER asked whether it was the intention of the Government to introduce a bill this session or next to establish in Ireland a complete system of registration of births, marriages, and deaths.

Lord NAAS said it was the intention of Government to introduce such a measure for Ireland as that referred to by the hon. gentleman.

### MEDICAL NEWS.

**ROYAL COLLEGE OF SURGEONS.**—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at the meeting of the Court of Examiners on the 4th inst. :—

ASHBY, JOSEPH FRANCIS, Olement's-inn.  
BABBAGE, WILLIAM BERRY, New Kent-road.  
CRAWFOOT, WILLIAM MILLER, Beccles, Suffolk.  
CROMPTON, FREDERIC, Bury, Lancashire.  
FRY, WALTER, Forest-hill.  
NASH, CHARLES SAMUEL, Box, Wiltshire.  
RINGROSE, ERNEST, Potter's-bar, Middlesex.  
WILKES, EDWIN, Salisbury.  
WILLIAMS, WILLIAM, Menai-bridge, Anglesea.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, June 3, 1858 :—

BARKWAY, ROBERT EDGAR EDWARD, Bungay, Suffolk.  
LAW, JOHN, Barnstaple, Devon.

#### DEATHS.

**ARNOTT.**—May 29, at Green Croft, Ecclefechau, N.B., Archibald Arnott.

**BUSCH, Professor.**—The Medical Faculty of the University of Berlin has sustained great losses this year, in the person of its celebrated physiologist, John Müller, whose reputation is world-wide; and in its distinguished Midwifery Professor, Dietrich Wilhelm Heinrich Busch, whose father was Professor of Medicine at Marburg, where he was born in 1788. Passing the earlier part of his life in the army, he was appointed Professor of Surgery at Marburg in 1814; but afterwards adopted the midwifery branch of the Profession. His renown as a teacher of this at Marburg became so great, that on the death of v. Siebold in 1827, he received the "call" to Berlin, while the son of his predecessor, now of Gottingen, took his place at Marburg. In Berlin he soon acquired the largest practice in this department, and was also the author of several excellent obstetrical works, which had a large circulation amongst students. Until his last illness he had enjoyed robust health, which enabled him to go through his laborious duties with activity and energy. This illness was acute rheumatism, from which he seemed to have well-nigh recovered, when he suddenly died from a supervening heart affection, in the 70th year of his age, and just on the eve of his 50 years doctorate-jubilee.

**CRAMPTON.**—June 10, at Dublin, Sir Philip Crampton, Bart.

**HILL.**—May 30, at Wiveliscombe, P. L. Hill, M.R.C.S. Eng. and L.S.A., 1824.

**HUMPAGE.**—June 4, at Hackney, Edward Humpage, M.R.C.S., aged 27.

**LUCAS-CHAMPIONNIERE.**—M. Lucas-Championnière died recently after a short illness, and at an early age, having taken his degree only in 1828 or 1829. He was the founder of the *Journal de Médecine*, a translation of which into English has just been commenced by Dr. M'Carthy.

**MARTEN.**—May 20, at Rochester, North America, William Marten, M.R.C.S.

#### APPOINTMENT.

Dr. P. Eade was appointed Physician to the Norfolk and Norwich Hospital on the 22nd of May last.

**THE EPIDEMIC OF VARIOLA AT BERLIN.**—During the month of March the epidemic increased in virulence. The police had notice of 805 cases, and of these 60 died. Of the 805, 659 had been vaccinated, 105 had not been vaccinated, and 41 unsuccessfully vaccinated. Of the fatal cases 16 had been vaccinated, 39 were unvaccinated, and in 5 the vaccination was uncertain. Thus 7.48 per cent. of all the cases proved fatal. Among the vaccinated the proportion was 2.42 per cent., among the non-vaccinated 37.14 per cent., and of the uncertainly vaccinated 12.19 per cent.

**RETIREMENT OF M. BEGIN.**—M. Begin being about to retire from his post of President of the Council of the Army, or Inspector-in-Chief, a committee was formed, consisting of MM. Lévy, Larrey, Hutin, and others, to invite him to a banquet on the occasion. This, with his well-known modesty, he has peremptorily declined, observing, "I have an invincible dislike for anything like a public exhibition. During forty-six years my career has been simple, retiring, and modest, and I am desirous that my retirement from the service may correspond to this. What I am desirous of, and have always had the ambition to do, is to leave among the meritorious and devoted body of military Medical officers a durable sentiment of esteem and affection. Happy shall I be if I may believe that it can discover in my long career some happy tradition as its guide. This would be quite sufficient for me, and no banquet could add to my satisfaction." After forty-eight years of a truly-devoted service, he retires from the army a poor man; the performance of his duties, in the most austere sense of the phrase, having been his sole object.

**THE CHOLERA IN FRANCE.**—The *Journal des Debats* has a short article on the cholera in France. The number of victims to this disease in 1854 is estimated at 150,000 only, but this is considered to be far below the real number of deaths. The deaths in the urban or town districts averaged 67 out of every 10,000 inhabitants, and in the rural districts 34 out of every 10,000. The mortality of the two sexes was pretty nearly equal in the towns, but in the country the number of female deaths exhibited a remarkable excess. The ravages of the disease throughout France were strikingly less in the first two "invasions" than in that of 1854; thus in 1832 the deaths from cholera are reckoned at 102,735 only, and in 1849 at 110,110, while in 1854 they rose to 150,000; but it is shown that the disease gains in extent what it loses in intensity.

**EXTREME OLD AGE.**—The following are facts as recorded in newspaper paragraphs :—Mr. James Nolan died upon the 24th of April, 1858, at Auchindrane, Carlow, Ireland, having reached the age of 115 years and nine months. He was born in 1742. All his faculties were preserved to him until his death, his sight being nearly perfect, and only his hearing defective. There is something more interesting in

these facts than merely the oldest subject of her Majesty, who had lived in the reigns of five Sovereigns of England. The lawyer could tell us the proofs which establish the date of the birth of Mr. James Nolan in 1742; the doctor could describe to us his constitution, habits, diet, and precautions; and lastly, the clergyman could give us an account of his moral dispositions—the most important considerations of all in regard to longevity. The remarks we have made upon the case of Mr. James Nolan apply equally to the case of a woman who, according to the report of the Registrar-General for the first quarter of this year, died the other day at Cawdor, in the county of Nairn, at the patriarchal age of 110 years.—*Glasgow Mail*.

**VACCINATION IN IRELAND.**—A bill of the Irish department of the Government empowers the committees of all dispensary districts in Ireland to divide the districts into so many "vaccination districts" as they may deem necessary and advisable, and to require the medical officers of the districts to attend at convenient times for the purpose of vaccinating all persons applying for the purpose. Boards of guardians are required to pay the Medical officers the sum of 6d. for every case of successful vaccination. The Sanitary Commissioners of Ireland in a recent report urge the immediate necessity of promoting vaccination in that country, as a general outbreak of the disease to which it is an antidote would decimate the population and be productive of the most frightful evils.

**ROYAL COLLEGE OF SURGEONS IN IRELAND.**—A meeting of the College was held on Monday, the 7th instant, when the following officers were elected to serve for the ensuing year, viz.:—*President*—James William Cusack; *Vice-President*—Christopher Fleming; *Secretary of the College*—Edward Hutton; *Council*—Sir Philip Crampton, Arthur Jacob, Thomas E. Beatty, William Hargrave, Andrew Ellis, Robert C. Williams, Robert Adams, James Barker, William Colles, John H. Power, Hans Irvine, James S. Hughes, Edward Hutton, Robert Pentland, Samuel G. Wilmot, Augustus E. Tabuteau, Thomas J. Mackesy, Auley P. Banon, Rawdon Macnamara.

**THE MEDJIDIE.**—The *Queen* has been pleased to grant to Deputy Inspector-General of Hospitals William Charles Humfrey, and Deputy Inspector-General of Hospitals William Cruickshank, M.D., Her Royal licence and permission that they may accept and wear the Insignia of the Imperial Order of the Medjidie of the Fourth Class: and Staff-Surgeon of the Second Class Alexander Douglas Taylor, M.D., the Fifth Class of the same Order, which His Imperial Majesty the sultan hath been pleased to confer upon them respectively, as a mark of His Majesty's approbation of their distinguished services before the enemy during the late war.

**THE FENS.**—In ancient times, when the fens were under water one-half the year, the ague was common every winter, and scarcely a house escaped this tertian visitor. The introduction of steam power enabled us to effectually drain our fens, and the ague, it was thought, had disappeared with the water: inundated fields and uncontrollable shivering were no longer to be our winter companions. The past has been one of the driest winters on record; for five months scarcely any rain fell, yet ague has been very prevalent—indeed, more general than it has been for a number of years. The chymists have had a strong demand for quinine, the *no plus ultra* of tonic remedies, and many of them have done a brisk trade in ague mixtures, ague pills, and ague pills, and ague wine.—*Stamford Mercury*.

**IRISH MEDICAL ASSOCIATION.**—The annual meeting of this body was held on Monday, at the Royal College of Surgeons, Dublin. The meeting, which was numerously attended, was presided over by Dr. Kingsley, of Roscrea, the President of the Association. Satisfaction was expressed that the two bills successively introduced into the House of Commons by the late Chief-Secretary for Ireland, Mr. Herbert, for the amendment of the Medical Charities Act, either of which would have had the effect of abolishing Medical inspection, had both been withdrawn, a result attributable to the energy and independence with which the profession in Cork had roused their brethren throughout the country, and a hope was expressed that a more favourable measure would be initiated by the new Secretary, Lord Naas.

On this subject a deputation consisting of representatives from various Medical Associations throughout the country, with the President of the Colleges of Physicians and Surgeons, and other Members of the Profession in Dublin, had waited on his Lordship on the 7th of April last. The association expressed their disapproval of the Vaccination Bill introduced by Lord Naas, and particularly of the provision that a fee of only sixpence should be paid for each successful case of vaccination, and after the election of officers for the ensuing year, the meeting broke up.

THE composition of the water supplied by eight of the water companies in the metropolis has been determined for the month of April by Dr. Robert Dundas Thomson, F.R.S. of St. Thomas's Hospital, and is represented in the subsequent detail by the Registrar-General, who says:—It is proper to mention that the water containing the largest amount of impurity, happened to be taken after a fall of rain, when a distinct alteration in the composition of water derived from the surface drainage of an agricultural country can usually be detected. In this detail one degree of impurity is equivalent to one grain of foreign matter present dissolved in the water per gallon. For the scale of comparison water about to be supplied to Glasgow from Loch Katrine, and water supplied to Aberdeen from the Dee, are introduced.

Companies.	Total Impurity. Gra. or deg.	Total Impurity. Gra. or deg.
Distilled Water . . . . .	0·0	—
Loch Katrine . . . . .	2·15	0·80
Aberdeen Water . . . . .	4·0	1·75
East London . . . . .	17·08	0·96
New River . . . . .	17·48	1·68
Kent . . . . .	27·29	3·62
Southwark . . . . .	17·80	1·08
Lambeth . . . . .	21·60	2·52
Chelsea . . . . .	19·00	1·80
West Middlesex . . . . .	19·92	1·96
Grand Junction . . . . .	20·12	1·72

All the specimens were derived from the main pipes, with the exception of that of the New River, which was taken from a private tap in King William-street, City, and the Kent Company's sample, which was obtained from a house in Meeting House-lane, Peckham.

## VITAL STATISTICS OF LONDON.

Week ending Saturday, June 5, 1858.

### BIRTHS.

Births of Boys, 765; Girls, 780; Total, 1545.  
Average of 10 corresponding weeks, 1848-57, 1465.

## TO CORRESPONDENTS.

A paper by Dr. Conolly, on Puerperal Mania, with four illustrations, will appear in our next Number.

A proof of Dr. Kramer's paper has been sent to Berlin.

Dr. Aveling's paper shall appear as soon as possible.

Mr. Crompton's cases shall appear.

The conclusion of Dr. Simpson's valuable paper on Metallic Sutures is in type, but it is unavoidably delayed until next week.

*Alpka, Saffron Walden.*—Students of the Grosvenor-place School hold dresserships at St. George's Hospital.

*R. R.*—Carpenter on the Microscope—Pillischer's Student's Microscope, seven guineas—Abel and Bloxam's Chemistry.

*A Reader of the Journal.*—Apply to Pillischer, instrument-maker, New Bond-street.

*Dr. A.*—The last report of the Kentucky Deaf and Dumb Institution says of the effects of intermarriages:—From ten to twenty per cent. of deaf mutes are the children of cousins.

*Mr. Johnstone.*—The committee are making an effort to open a separate Lock Hospital for male patients in some central position in London, and have announced subscriptions to the amount of £1800 for that special purpose.

*M. R. C. S., Norwich.*—We cannot say if the homœopath, Dr. Bell, formerly practised in Norwich, or if the report that he signed a lunacy certificate as M.D., Licentiate of the College of Physicians, be or be not true.

*A Subscriber.*—The appointment of Registrar of Births and Deaths is made by the Registrar-General. The emolument depends upon the number of cases registered. The Registrar is not obliged to attend at the house where the death has occurred.

*A Naval Surgeon.*—Naval and military Surgeons, who have not passed the examination at Apothecaries' Hall, have not a legal right to practise as Apothecaries in England and Wales. They cannot recover in a Court of Law any charges made by them as Apothecaries.

*An Inquiring Student.*—It is a very difficult thing to determine exactly the circumstances under which an inquest ought to be held. In the case described, we think that the death was so sudden and unexpected that an investigation was necessary. The emptiness of the heart, observed at the post-mortem examination, was no doubt due to syncope, which seems to have been the immediate cause of death.

**ERRATUM.**—It was Mr. Wade, of Birmingham, not Mr. West, referred to by Dr. Camps as the author of a paper on Diphtheria.

#### DISINFECTANT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In reply to the inquiry of your correspondent "Inquisitor" I would suggest that he refers to "Condy's Disinfecting Fluid."

I am, &c.

B. R.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The Disinfecting Fluid "Inquisitor" is wishing to discover through your readers, is Condy's, of Battersea Chemical Works. It is a permanent of potash, and has been much extolled for its disinfecting and deodorizing properties.

I am, &c.

St. Mary's Hospital, June 8.

—See Advertisement this week.

AUG. TALBOTT.

#### TO THE NERVOUS AND DEBILITATED.

From the "Aberdeen Herald" of May 29th, 1858:—

CHARLES WATSON, M.D., Fellow and Honorary Vice-President of the Imperial African Institute of France, and Physician to the Bedford Dispensary, 27, Alfred-place, Bedford-square, London, continues to issue, on receipt of 6 stamps, "The Guide to Self-Cure."

"The first man of the day in these complaints."—Medical Review, July, 1856.

"The true Guide to those who desire a speedy cure."—University Magazine.

"The New American Discovery shows the absurdity of the English mode of treating such complaints; will prove a blessing to the afflicted, who may safely and easily regain pristine health by adopting the means presented."—Evening Sun.

**CAUTION.**—Dr. Watson, to distinguish himself from unqualified parties, refers with pleasure to his qualifications—viz. Diplomas and the "Medical Directory."

#### POOR-LAW SUPERANNUATION FUND.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I have this day received the draft of a bill, intitled "An Act to Authorize the Establishment of a Poor-law Officers' Superannuation Fund." There appear to me many reasons why I cannot assent to the bill in its present form.

1. I object to any person being compelled to admit of a certain per centage being deducted from the paltry remuneration paid for the onerous duties required in any office under the Poor-law Board, and which it is admitted in the circular enclosed with the draft of the bill, is scarcely sufficient to "maintain their respectability while in office;" especially that a uniform deduction of 2½ per cent. should be made, whilst there is no proper ratio of the payment of Medical Officers, the remuneration varying, as Mr. Griffin, of Weymouth, has shown, from a few pence to 16s. per case. This certainly requires to be altered, before we should all be compelled to admit of the same per centage being deducted from our salaries.

2. I think if there is an actual necessity for this bill, and that this is the proper period for establishing it, it does not require to be made compulsory. Why should it not be optional? It is repulsive to the feelings of a "free-born Englishman," to be compelled to do anything. Let the benefits to be derived from a Poor-law Superannuation Fund be freely made known, and, if it is required, it will soon be established; but to be compelled to admit of a deduction from a salary, gives a feeling of disgust to

the thing at once. We all know our salaries are paltry enough, and many of us have dispensed with many comforts, if not necessities, to enable us to provide ultimately for our wife and family by the payment to a "Life Assurance" of established repute: then why compel us to belong to another, which has the same objects in view, but with a degree of doubt as to its proceeds becoming substantial, and the payment towards the funds of which we can ill afford?

3. If it is to be compulsory to contribute to this Superannuation Fund, surely the per centage to be deducted ought to vary according to the amount of our salaries. The man receiving a small salary could not afford the deduction of 2½ per centage so well as a man receiving a high salary, and why should a young man commencing an appointment at 25 years of age pay the same amount of per centage as one at 45? One may have to subscribe thirty years and the other ten.

4. If it is advisable to establish this Fund, I think the more it is kept apart from the Poor-law Board the better. We all know how little interest this Board takes in their Medical officers, who, while they allow them to be ground down by the Local Boards of Guardians to the lowest farthing, compels them to perform their onerous duties to the utmost; and when tyrannised over, show no shadow of justice or redress. How, then, can a Medical man voluntarily place more power in the hands of such a body? How are we to be certain that from some spleen of a Local Board the Committee of that board may not magnify something into neglect of duty, and then by appealing to the Poor-law Board (who never oppose the Guardians), the gentleman who has subscribed, perhaps for years, may, at the option of these honourable Commissioners, be mulcted of all the contribution he has made, and lose his income in the bargain. I think it were much better for all of us to belong to some old-established Life Assurance than a Superannuation Fund, the stability of which must be uncertain, and which, it is proposed, should be connected or rather ruled over by those who have always appeared to tyrannise over us. Hoping you will allow the free discussion of this subject in your invaluable periodical,

I am, &c.

A CONSTANT SUBSCRIBER.

COMMUNICATIONS have been received from—

Professor SIMPSON, Edinburgh; Dr. ANDREW SMITH; Mr. PRESCOTT HEWETT; Dr. RADCLIFFE; Dr. MACLEOD, Glasgow; Dr. EADE; Dr. MACMILLAN, Hull; Mr. KNAGGS, Huddersfield; Mr. REED; Mr. RIVERS; Mr. GORDON; Mr. TALBOTT; Mr. HEWITT; Mr. ROBERTSON; Mr. PROPERT; Mr. S. SMITH; Mr. H. SMITH; Mr. CATTIN; Mr. FOX; Mr. J. B. BURNETT; Mr. W. CALCOTT; Dr. HIGHMORE; Dr. BUCHANAN; Dr. B. SMITH; Mr. GRIGG; Mr. SEABROOK; Dr. J. FORSYTH; Dr. J. ## APPOINTMENTS FOR THE WEEK.

### June 12. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m.; Charing-Cross, 1 p.m.  
ROYAL INSTITUTION, 3 p.m.: Edwin Lankester, M.D., F.R.S., F.L.S., "On the Vegetable Kingdom in its Relations to the Life of Man."

### 14. Monday.

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.; Orthopaedic Hospital, 2 p.m.

### 15. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

### 16. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Orthopaedic Hospital, 2 p.m.  
NORTH LONDON MEDICAL SOCIETY: (Council Meeting) 7 p.m.  
MICROSCOPICAL SOCIETY, 8 p.m.

### 17. Thursday.

Operations at St. George's, 1 p.m.; Middlesex, 12½ p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.  
CHEMICAL SOCIETY, 8 p.m.  
ROYAL SOCIETY, 8½ p.m.  
LINNEAN SOCIETY, 8 p.m.

### 18. Friday.

Operations at the Moorfields Ophthalmic, 10 a.m.; Westminster Ophthalmic, 1½ p.m.; Great Northern, 2 p.m.

## EXPECTED OPERATIONS.

King's College Hospital.—The following operations will take place this day (Saturday), at 2 o'clock:—

Cleft palate; removal of dead bone from ankle. By Mr. Ferguson.

## Clerical, Medical, and General

SPECIAL NOTICE.

LIFE ASSURANCE SOCIETY,  
13, ST. JAMES'S-SQUARE, LONDON, S.W.  
ESTABLISHED 1824.

All Persons who effect Policies on the Participating Scale BEFORE JUNE 30th, 1853, will be entitled at the NEXT BONUS to one year's share of Profits beyond later Assurers.

Proposals should be forwarded to the Office before June 20th.

The last Annual Report, as also a statement of the SIXTH BONUS declared in January 1857, setting forth in detail the whole state and affairs of the Office, and especially the benefits which will hereafter accrue to Persons now Assuring, can be obtained of any of the Society's Agents, or from the Office.

GEORGE H. PINCKARD, Actuary.  
GEORGE CUTLIFFE, Assistant Actuary.

13, St. James's-square, London, S.W.

N.B.—The usual COMMISSION allowed to Medical Men introducing Assurances direct to the Office.

## Medicine Chests.

MARSH & GRIFFITHS,  
LATE

SPRINGWEILER,

2, DUKE-ST., SMITHFIELD, LONDON, E.C.  
Chests from 8s. 6d. to £10 Ship Chest  
according to Act of Parliament.  
Established 50 years.

## W. Twinberrow begs to draw the

attention of the Medical Profession to his EXTRACT of INDIAN HEMP, prepared expressly for him at Calcutta, its peculiar sedative properties being so beneficial where opiates are inadmissible. Also to his MEDICINAL EXTRACTS, prepared from the fresh plants (Hyoscyamus Niger, Conium Maculatum, Atropo, Belladonna, Cotyledon Umbilicus, etc.) Also to his Liq. Taraxiel, Liq. Galli Aparinis (a valuable alternative), Liq. Parisetaris (diuretic), and Liq. Belas (prepared from the *Aglio Marmelos*, or Indian Basil), for dysentery and diarrhoea. W. T. has a large supply of INDIAN BAEI on hand. 2, Edwards-street, Portman-square.

BOUDAULT'S PEPSEINE imported in original bottles.

## ELECTRICITY

PULVERMACHER'S MEDICAL ELECTRO-GALVANIC CHAINS—for Rheumatism, Indigestion, and Nervous and Paralytic Complaints, &c. &c. The profession have in these Chains the best, simplest, and most effective means of applying Galvanism. No pain is felt, and the patient can, without attendance, use them himself with efficiency. The popularity they have obtained in almost all parts of the world, and the numerous cures they have effected, together with the eulogiums passed upon them by the most eminent of the faculty, suffice for any further details. See the works of De la Rive, Becquerel, Duchenne, Pouillet, Ganot, Du Moncel, and the medical and scientific periodicals. Adopted by the Academie de Medicine, Paris, and by all similar institutions in Europe; also rewarded at the Universal Exhibition. £10,000 damages. Both the High Courts of England and France condemned Mr. C. Meinig (ex-agent) in this sum for infringing the inventor's rights. Let counterfeits therefore, be cautious.—Chains to be worn on the body, 5s. and 10s. 6d.; the 15s., 18s. and 22s., are the most useful. Free per post. Batteries, £1 10s. to £3.—J. L. PULVERMACHER & CO., 73, Oxford-street, (adjoining the Princess's Theatre,) London.

## The Sydenham Trousers, 17s. 6d.;

COATS, 33s.; and WAISTCOATS, 8s. 6d.—It is well known how great an influence is exercised upon the health by the mode of dress. Many disorders, and still more of the common indispositions or irregularities, can be distinctly traced to imperfect adaptation of the clothes to the functions of the body and the limbs. This is true of adults as well as of children, though, perhaps, not to the same extent. The Sydenham construction of the whole attire is directed to secure a perfect fit in all positions without restraint, strain, or incumbrance, so that the limbs retain as free play as if in PURIS NATURALIBUS. The Boy's Complete Suit (24s.) is also eminently adapted for those purposes. The material and workmanship are the best which can be commanded. The assortment open for selection is immense, and includes all that is most fitted for the season. The assortment of Sydenham Alpaca Overcoats (12s. 6d.) for Summer wear deserves attention, as these goods have been made with unusual care.

SAMUEL BROTHERS, Merchant Tailors, 20, Ludgate-hill.

## Condy's Patent Fluid contains nascent

Oxygen, which is NATURE'S DISINFECTANT, for instantly and permanently removing all unpleasant smells. It has no smell—is not poisonous—will not stain when diluted—may be used for purifying water for drinking. Its colour prevents the possibility of mistake in use. It is recommended by the General Board of Health, &c. &c.

Sold by the Trade in bottles, at 6d., 1s., and 2s. each, or at 5s. per gallon. MANGANATE or PERMANGANATE of POTASH as ESCHAROTICS.

Central Retail Depot, 97, Fleet-street, London, E.C., whence samples of 1 dozen ½-pints, or ½-dozen pints, or ¼-dozen quarts of the Fluid, and 4 oz. or upwards of the Manganates or Permanganates, will be forwarded, carriage paid, to any part of the kingdom, at the retail prices, on receipt of stamps for the amount.

This is notified, in case of any difficulty in obtaining either of these substances through the usual sources.

Wholesale of the Patentee, Battersea, Surrey, S.W.

## Wines from the Cape of Good Hope.

W. and A. GILBEY, 397, Oxford-street, importers of the finest Wines, which Her Majesty's Government admits at half duty. Port, Sherry, Madeira, Marsala, &c., all 20s. per dozen. Two Samples for 12 stamps. Excellent Brandy, 80s. per dozen. For the purity of our Cape wines, see Dr. Letheby's analysis. Cross checks, "Bank of England."

## The Medicated Cod Liver Oils,

comprising  
OLEUM MORRHUE CUM QUINA.  
OLEUM MORRHUE CUM FERRI IODIDO.  
&c. &c. &c.

Prepared only by SAVORY and MOORE, 143, New Bond-street.

## Liquor Pepsinæ.—A Convenient and

EFFICACIOUS PREPARATION BY  
SAVORY and MOORE, 143, New Bond-street.

## WINES FROM SOUTH AFRICA.

Denman, Introducer of the South AFRICAN PORT, SHERRY, &c., 20s. PER DOZEN, BOTTLES INCLUDED.

The well-established and daily-increasing reputation of these Wines in the public estimation renders any comment respecting them unnecessary. A PINT SAMPLE OF EACH FOR 24 STAMPS.

Wine in cask forwarded free to any Railway-station in England.

EXCELSIOR BRANDY, PALE OR BROWN, 15s. PER GALLON, OR 30s. PER DOZEN.

Terms Cash. Country orders must contain a remittance. Cross cheques, Bank of London. Price Lists forwarded on application.

JAMES L. DENMAN, 66, FENCHURCH-STREET.

## BROUGHAM'S.

Kinder, M'Naught, and Smith, MANUFACTURERS, WORCESTER, beg respectfully to invite the attention of professional men to their improved Medical Broughams, as under:—

Width of Seat.	Weight.	Price.
3 ft. 5 in. . . . .	7½ cwt. . . . .	85 Guineas.
3 ft. 6 in. . . . .	8½ cwt. . . . .	95 Guineas.
3 ft. 7 in. . . . .	9 cwt. . . . .	100 Guineas.

The latter, including a segmental front, with seat for third person.

These Carriages are constructed, by the aid of machinery, of the best material, are of excellent workmanship, and particularly adapted to the wants of medical men, either in town or country. Drawings and other particulars forwarded on application.

## Great Saving in the Purchase of Six

GROSS of NEW MEDICAL GLASS BOTTLES and PHIALS, assorted to suit the convenience of Purchasers, at ISAACS and SON, Medical Glass Bottle Manufacturers.—London Warehouses, 24 and 25, Francis-street, Tottenham court-road, London, W.

	s.	d.
6 and 8 oz., any shape, plain, or graduated . . . . .	8	0 per gross.
3 and 4 oz. ditto ditto . . . . .	7	6 do.
1 oz. Moulded Phials . . . . .	4	6 do.
1 oz. ditto . . . . .	5	6 do.
1 ½ oz. ditto . . . . .	6	0 do.
2 oz. ditto . . . . .	7	0 do.

NOTICE.—S. ISAACS and SON beg to inform the Medical Profession that they have REMOVED to larger premises as above, and hope to be favoured with their commands. A remittance not required till the goods are received. Packages free. Delivered free within seven miles. Post-office Orders payable to "S. Isaacs and Son," at Tottenham-court-road. Bankers: Unity Bank.

Or SACHARATED CAPSULES, approved of by the French College of Physicians, successfully administered in the Paris and London Hospitals, and acknowledged by them to be the best remedy for the cure of certain diseases. (See the "Lancet" of 6th November, 1852; "Medical Times" 10th December, 1852; a copy of which will be forwarded on application.) Price per 100, 4s. 6d.; 50, 2s. 6d.

To be had of the Inventor, GABRIEL JOZEAU, sole French Chemist, 49, Haymarket, London, whose name is printed on the Government stamp, and of all the principal Chemists of England.

## ORIGINAL LECTURES.

LECTURE ON  
NON-CONGENITAL TALIPES VALGUS.DELIVERED AT THE  
Grosvenor Place School of Medicine,  
(ADJOINING ST. GEORGE'S HOSPITAL.)By WILLIAM ADAMS, F.R.C.S.,  
Surgeon to the Royal Orthopaedic Hospital, Lecturer on Surgery  
at the Grosvenor Place School of Medicine.

GENTLEMEN,—The last lecture was devoted to the consideration of the congenital form of talipes valgus, or flat-foot, a deformity which I told you occurred both as a congenital and non-congenital affection. I will now, therefore, proceed to describe the non-congenital form of valgus. Much that has been said in the description of congenital valgus will equally apply to the non-congenital form; but although a general resemblance in the external character, and a still closer correspondence in the deviations in the relative position of the bones, exist in these two forms of the deformity, yet the non-congenital valgus is found to exist under such a great variety of circumstances, and is a deformity which gives rise to so much personal inconvenience, and, moreover, is of such frequent occurrence, that it imperatively demands the most earnest attention of the Surgeon.

EXTERNAL CHARACTERS.—The only essential external character of non-congenital valgus is a flattened condition of the longitudinal and transverse arches of the foot, from which its vulgar appellation of flat-foot, or splay-foot, is derived. The inner margin of the foot comes flatly in contact with the ground, when the weight of the body is borne upon the foot, and in severe cases without the addition of this weight; but except in severe cases of long standing, or in spasmodic cases, the outer margin of the foot is not raised as in the congenital form for this reason:—Non-congenital valgus, in its ordinary form, depends upon a passive yielding of the strong tarsal ligaments in the sole of the foot, and a feeble or over-stretched condition of the muscles; there is no active muscular contraction; the foot is, therefore, mechanically moulded into its flattened and distorted condition; but in the congenital form, the anterior part of the foot is drawn upwards and outwards, and the tuberosity of the os calcis also generally elevated, by active muscular condition, so that the outer margin is uplifted, as shown in fig. 58. The natural convexity of the instep is diminished to an extent proportionate to the flattening of the longitudinal and transverse arches. The inner malleolus is more prominent than natural, in consequence of a yielding and elongation of the deltoid ligament, and is also nearer to the ground, in consequence of the flattening of the arches of the foot; so much is this apparent, that a child with flat-foot is commonly said to “walk on the inner ankle.”

A little below and in front of the inner malleolus are two bony prominences, with a depression between them; one formed by the inner portion of the head of the astragalus, left exposed by the altered position of the navicular bone, and the other by the tuberosity of the navicular bone. The former is most conspicuous in children who, when affected with this deformity, are often said by their parents to have two ankle-bones, or supposed to be double-jointed. The foot is not only generally flattened, but is somewhat elongated, as a consequence of the sinking of the longitudinal arch, and is more or less everted; the eversion being most conspicuous when the foot is used in walking. During progression the weight is thrown on the inner margin of the foot, which, being already depressed and the foot everted, the ankle-joint is called but little into play; flexion and extension of the foot from the ankle-joint are very imperfectly performed, hence the loss of elasticity in walking particularly noticeable in the flat-footed individual.

As a consequence of the ankle-joint being thrown out of use, additional changes gradually take place, which add to the external appearances of the deformity in a late stage; structural shortening of the muscles of the calf takes place, they adapt themselves to their required length, and, as we express it, contraction of the tendo-Achillis supervenes.

Elevation of the tuberosity of the os calcis takes place, and depression of its anterior extremity, together with the head of the astragalus, to a corresponding extent; and as the anterior part of the foot, in this late stage of the deformity, has become not only more everted and forced upwards by long-continued progression, but is rigidly held in this position by the contraction or adapted shortening of the anterior and outer muscles, the result is that the natural arch of the foot is really reversed, the foot being bent upon itself, as it were, from the transverse tarsal joint, in a boat-shape or canoe-like form.

This extreme degree of distortion, however, is only met with in non-congenital cases when very severe and of long standing. I have one such case now under my care in a man who, for many years, has earned his living as a porter, carrying heavy weights, but is now quite incapacitated from following his occupation. I expect to make a perfect cure of this man, so that he may even resume his standing and carrying employment.

The influence of contraction of the tendo-Achillis in modifying the external appearances of this deformity, and the importance of recognising the transverse tarsal joint as the great centre of motion in the production of the deformity, I have particularly insisted upon in the description of congenital valgus, to which I would refer you.

Special effects of this deformity.—Talipes valgus is undoubtedly the most painful and seriously-inconvenient deformity of the foot. When even of moderate severity, it frequently deprives the sufferer of the power of walking more than a short distance, or of standing for any length of time, and therefore incapacitates him from many of the ordinary duties and occupations of life. Congenital valgus, I showed you by the tables, more frequently affects one than both feet; but non-congenital valgus more frequently affects both feet; and as it is commonly either produced, or undergoes serious increase, between the ages of 14 and 20, and occurs much more frequently in boys than girls, the effects are of the more serious consequence.

MORBID ANATOMY AND ETIOLOGY.—So far as this relates to the deviations in the relative position of the bones, and the mechanical condition of the foot, the morbid anatomy of non-congenital valgus is identical with that of the congenital form, to the description of which given in the last lecture I would therefore refer you. But I would especially impress upon you the fact, that whilst in the congenital valgus the anterior part of the foot is drawn upwards and outwards, with elevation of the outer border of the foot, by the active contraction of the muscles—at least, this I believe to be the explanation in a great majority of cases—the yielding of the plantar ligaments being a secondary phenomenon; the non-congenital form generally depends primarily and essentially upon a yielding of the ligaments which connect the tarsal bones in the plantar aspect, and normally maintain the longitudinal and transverse arches of the foot.

In the non-congenital form there is also generally, but not invariably, a co-existing muscular debility; but all the contraction of muscles, which comes on at a late period and gives to the foot much of its rigidity in the deformed position, and necessitates the division of tendons, is a secondary phenomenon, and depends upon adapted shortening of the muscles.

Non-congenital valgus, however, occurs under such a variety of circumstances, depending upon such very different causes, and the anatomical conditions of the muscles, ligaments, and other soft tissues surrounding the joint vary so much, according to the causes producing the deformity, that it would be impossible to give you a complete description of the morbid anatomy at once applicable to all these conditions. Therefore, instead of discussing the morbid anatomy and etiology separately, as we have done in treating of the other deformities, it will be better to arrange all the cases of non-congenital valgus into different classes, according to the causes producing the deformity, and to mention the anatomical peculiarities of each class.

In accordance with this plan, all the cases of non-congenital valgus appear to admit of arrangement into six classes, viz:—

1. Valgus depending upon ligamentous and muscular debility.
2. Rachitic valgus.
3. Paralytic valgus.
4. Spasmodic valgus.

## 5. Traumatic valgus.

6. Valgus consequent upon disease of the ankle-joint or surrounding tissues.

*Class 1.—Arising from Debility.*—Non-congenital valgus occurs at different periods of life, most frequently in childhood and youth, but it is of by no means uncommon occurrence in young adults.

In children we frequently see the foot turn outwards, and the arch become depressed from the superincumbent weight. A few months after they have begun to walk, and at a later period it is frequently associated with knock-knee. This condition, however, is generally recoverable, frequently without any artificial assistance, and does not pass into a persistent deformity; but if neglected, and a feeble constitutional condition remains, it may lay the foundation of a confirmed valgus.

In boys and girls, but more frequently in the former, of delicate constitution and lax fibre, between the ages of 14 and 18, when growth is rapid, flat-foot frequently becomes developed, and remains as a persistent deformity unless removed by art. In girls, the constitutional causes above mentioned more frequently predominate; but in boys circumstances arising from their occupations which, in the working classes, frequently compel them to stand from twelve to fourteen hours every day, and in addition oblige them to carry heavy weights, act even more powerfully than the constitutional causes. Every week, boys, who from this deformity are incapable of following their ordinary occupations, apply at the Orthopaedic Hospital for relief. In some cases, these boys present no indications of muscular or general debility; but then the usual history is that the feet had always been rather flat—the condition I have just described as existing in childhood never having been removed—and in consequence of some fatiguing occupation to which the boy had not been accustomed, such as waiting at coffee-houses, errand-boy, carrying out goods at butchers, bakers' or grocers' shops, standing in factories, and especially in hot rooms, the feet had become rapidly worse and painful, so that he has been obliged to leave his situation. This deformity, however, is by no means confined to the working classes, but is frequently met with among school-boys, junior city clerks, and cadets; in the latter class the drilling, marching, and carrying of guns evidently tend to produce the deformity, or more frequently to increase when it already exists in a slight degree.

In adults flat-foot frequently becomes a confirmed and persistent deformity, having generally existed in a slight degree from an earlier period, and been neglected in consequence of the absence of inconvenience—under circumstances similar to those above described, to which boys are especially subjected. I have been informed that a considerable number of policemen are annually discharged from the force in consequence of being incapacitated from their duties by flat-foot. And although great care is taken not to enlist flat-footed men into the army, soldiers are not unfrequently obliged to leave the service from this cause. Waiters at taverns are almost proverbially flat-footed.

*Class 2.—Rachitic valgus* is, at the time of its production, essentially similar to the form I have just described as depending upon ligamentous and muscular debility, but becomes of a more severe and intractable nature in consequence of alterations occurring in the form of the bones. It is always associated with rachitic curvature of the long bones, especially with the sharp, flattened, anterior curvature of the tibia and fibula in their lower and middle thirds. Rickets being an affection peculiar to childhood, rachitic valgus can only take place at this period of life, and, like the other deformities of rickets, remains as a persistent condition after the spontaneous cure of the disease and solidification of the bones. This is the only variety of non-congenital valgus in which the bones become materially altered in form, and the readiness with which the softened bones mould themselves to the distorted position of the foot, materially adds to the intractable nature of this deformity, as may be seen by examining the adult rachitic skeletons in museums. The best specimen I know of exists in the museum of the Grosvenor-place School, and was the property of my late colleague, Mr. Pilcher.

*Class 3.—Paralytic valgus.*—In that peculiar and obscure form of paralysis, which occurs only in childhood, and furnishes us with so large a proportion of all the non-congenital deformities of the foot, and which I have already described to

you under the title of Infantile Paralysis (see *Medical Times and Gazette*, December 16, 1855), you will remember that I pointed out to you, as one of its leading characteristics, the frequency with which single muscles, and groups of associated muscles become suddenly paralysed. I stated to you that the anterior tibial is sometimes the only muscle thus paralysed, and in this you will at once see the explanation of the fact that in these cases the foot becomes everted and valgus produced. Occasionally, though rarely, the tibialis posticus muscle is paralysed simultaneously with the anterior tibial muscle, and in such cases valgus is more quickly produced. Sometimes the muscles of the calf, as well as the tibiales anticus and posticus muscles are also paralysed, the extensor longus and peronei not being involved; in such cases the tuberosity of the os calcis falls down, and calcaneo-valgus is produced, a most intractable deformity. It is found, as matter of experience, that paralytic valgus very frequently co-exists with paralytic-equino-varus of the opposite foot.

*Class 4.—Spasmodic valgus.*—This is undoubtedly the rarest form of non-congenital valgus, but it does occasionally occur in the class of cases I have already described to you as *Deformities with rigid muscles* (see *Medical Times and Gazette*, October 27th, 1855), generally consequent upon fits or convulsions during teething, and this description I illustrated by a case which furnished the best marked example of spasmodic valgus I have ever seen. (See fig. 4, *Medical Times and Gazette*, November 24, 1855.) I have explained to you that spasmodic affections generally produce talipes equinus, or equino-varus, for the reason that all the muscles of the leg being affected, those of the greatest bulk, the strongest muscles, gain the ascendancy, just as in the rigor-mortis, the foot always assumes the position of equino-varus.

*Class 5.—Traumatic valgus.*—Persistent eversion of the foot is a very frequent result of injuries involving the ankle-joint and the lower extremities of the tibia and fibula, such as fractures of these bones, or fracture and dislocation combined. In its worst form I have seen it in one instance after unreduced dislocation inwards, with fracture of the fibula. In these cases, eversion of the foot from the ankle-joint is first produced, a condition different from that which I have described as essential to valgus, in which I recognise the transverse tarsal joint as the principal centre of motion. However, in these traumatic eversions of the foot, the arch gradually gives way in consequence of the weight of the body being thrown upon the inner border, and a true valgus is produced, in consequence of which the patient is sometimes unable to walk more than a very short distance, even some years after the accident.

Before leaving this class of cases, I would merely mention a very common error for the sake of correcting it. Talipes valgus is frequently supposed by the patient to have been produced by a sprain—either a sprain or rheumatism is the cause to which this deformity is most frequently assigned by the patient. No doubt a flat foot is very susceptible of slight injuries, and easily sprained; and then as rapid increase is common in boys under the circumstances of occupation, etc., above mentioned, the effect is excusably attributed to a sprain. The pain suffered really depends upon the stretching of the ligaments during the increase of the deformity.

*Class 6.—Valgus consequent upon disease of the ankle-joint, or surrounding tissues.*—Persistent eversion of the foot, which subsequently becomes flattened in the form of valgus, is a common result of rheumatic and other chronic inflammatory affections of the ankle-joint, and also of strumous abscesses in the neighbourhood of the joint, periostitis, caries or necrosis of the fibula, etc. The causes named, therefore, either directly or indirectly affect the joint in the production of the deformity, and the prognosis and treatment of such cases will vary accordingly.

(To be continued.)

**A NEW METAL.**—Mr. Joseph Jones, of Bolton-le-Moors, states that he has discovered the perfect metal sulphurium, which is of the same class as arsenicum, silver, aluminium, etc. Oxide of sulphurium is the refuse of the manufacture of sulphuric acid from brimstone, and has no commercial value; persons being paid for carting it away. In its refuse condition it has almost the specific gravity of iron, and the atoms are very fine, malleable and ductile.—*Miners' Gazette*.

## ORIGINAL COMMUNICATIONS.

## THE PHYSIOGNOMY OF INSANITY.

By JOHN CONOLLY, M.D. D.C.L.

Consulting Physician to the Hanwell Asylum.

## No. 8.—PUERPERAL MANIA.

"The same face!" "Bring me back the same face!" Simple expressions these would seem to be, quoted by Lavater, uttered by some simple and sensitive German parent, as his only request, when taking leave of his son, who, in the morning of life, is quitting a quiet home of affection for all that awaits him in the wide world. But the simple words dwell with us, and we perceive that there is deep meaning in them. Passions, good or bad; and trials and struggles; and pain and sorrow; and Time—will all write their peculiar characters on that youthful candid face; characters which death alone, with its effacing fingers, will take away; nay, which will still for a brief period survive, and dignify or mar the immovable face of death itself.

This strange writing on the human face soon begins; and it goes on as long as intellectual and moral life lasts. The transient griefs of childhood, and even the crueler sorrows of school days, although schoolmasters have not yet learned that boys, as well as maniacs and horses, may be managed without brutality, leave no indelible traces; for the attention is at that early period easily attracted to new objects; and the imagination makes perpetual excursions in advance of present events. So, the angles of the mouth remain still level; no perpendicular wrinkles yet mark the phrenological region of individuality; and in the corners of the eyes there are yet no furrows formed by tears. The first facial impressions are those of after-study, or of premature care or premature toil, and these are as various as their causes, solemnizing the countenance of the student of truth in science or morals, or carving betwixt some lines, faint but discernible, indicating the over-worked in body and mind. For twenty years more, or even thirty, the face is the face of the mature man; the impress of important thoughts there, but the beauty of youth not gone. The painter or the sculptor may yet copy the complexion or the form and features of the face, and its full expression, so as to perpetuate the man as he was before Time began to delve his parallels in the brow. The colour of early youth may have faded, but a healthy freshness long remains; and, where the thoughts are unselfish, and the heart still pure, the joyous smile of those whose minds are yet unclouded by the shadows of coming events still irradiates the features. Manhood has succeeded, but with noble discourse of reason, and energies prompting to action; and now in the human face divine are imprinted combinations of beauty and strength, and godlike apprehension; or, on the other hand, the slowly drawn lines of creeping and engrossing selfishness and cunning and cold avarice, may begin to be detected even amid features of general beauty. Thus some men, although early withdrawn from transient life, and withering and dying ere middle age, live long enough to survive all youth's freshness of look, as well as all freshness of heart; and expire, merely lamenting that death closes some prospect of gold, or of mortal possessions and privileges: their pinched features more and more closely drawn together, as if to exclude the approach of more generous movements; and such features, so impressed, make death hideous; which naturally it is not. Mean and evil thoughts alone make it so. Canova, after a life of devotion to the Beautiful, and who so often embodied it in sculpture, which is allied to all that is sublime in poetry, was visited in the mortal hour with visions unearthly, and perhaps divine. He exclaimed, more than once,—"Anima divina e pura!"—and his features, after death, seemed to be such as we hope to meet in the "solemn troops and sweet societies" of heaven. Others of noble stamp, also, are seen prematurely, as we creatures of a day deem it, to die out uselessly; but yet seem to end their few years of promise with better retrospections, and with anticipations greater still; their fading earthly hopes catching some orient tinge beyond death's night. But, in some shape or other, when manhood has been attained, time has begun to set its indelible stamp on us all. In all who survive the period

of life, when, not consciousness, but the almanac, tells us that fifty years are passed and gone, every face, of man or woman, becomes more and more a book in which the life and thoughts are written in hieroglyphics, to be deciphered by those who have acquired skill in such reading. Almost at a glance we discern the signs and quaint shapes of habitual thoughts and occupations, of station and rank, of command or obedience, of conscious wealth, and all the varieties of broken-down respectability; of intellectual greatness and calmness, or of vain assumption, or of brazen pretension; and indeed of all the differential gradations of social and mental life, down to the worn face of ignominious toil, and to the unmistakable abjectness of nature or position, from which the eyes, even of the good and kind, turn painfully away.

In the meantime old age keeps steadily advancing, although usually considered so distant that its voice startles those who find it close at hand, and who are unwarned by failing faculties, or even by the ever-accumulating wrinkles which have curiously usurped all the face that was once so smooth and unruffled. Year after year the sculpture of age goes on. Friends who meet after forty years' separation do not recognise one another. Every subsequent twelvemonth has left its trace in some feature or another. The mouth, once a double arc, expressive of what Medical prose cannot convey, has perhaps become a stereotyped sorrow, with lines drawn down laterally from its corners. There are griefs written in the eyes which have never been expressed in words. Thousands of intersecting lines are scribbled over the cheeks, as if a thousand elves had been employed to vary them. The fairest and broadest and loftiest forehead presents ugly lines, the shabby work of daily troubles, and of those especially which fall on defenceless senility. Yet the eyes, though grief-worn, long retain something of their immortal light, still remaining lustrous and noble, when a great and good soul shines through them to the latest breath; but nevertheless twinkling cunningly and ominously, in those whose mortal sight has been ever bent on the rich, base pavement of the world.

Such are the usual footsteps and impressions of the ordinary feelings, actuating the minds of the majority of persons in their progress through the allotted years of man on this preparatory globe. But when a mind becomes not merely excited or disturbed, not merely anxious or sorrowful, or even exclusively devoted to an engrossing passion, but actually deranged in its operations, these traces of long workmanship are generally all at once and curiously modified. The wandering attention, the fragmental memory, and the wild imagination, suspend or throw into confusion all the ordinary pursuits and offices of life of the individual; and no less usurp the control of the facial muscles, in various and remarkable degrees. The same circumstances modify nearly all the voluntary muscular actions of the body, influencing the movements of the arms and legs, and producing oddities in the mode of doing common things, as well as in the adjustment of dress; so that a man's whole exterior becomes indicative of his interior commotion, or of his disordered mind. Such indications are usually obvious, and, to an observer of the infinitely diversified figures met in the streets of London, quite familiar. Oddities of appearance and of costume are there occasionally beheld, which are scarcely to be found in the orderly and well-regulated wards of modern asylums for those avowedly mad; and which, as yet, neither the novelist nor the painter have attempted to describe.

When our observation, however, is limited to the face of a lunatic in the early stages of insanity, certain modifications of natural expression are usually observed; some of them so peculiar, and some so transient, as to defy photography, and to make a verbal description of them difficult; others observable by every one who can observe at all. When a man whom we meet daily in society, or in some associated duty, is becoming maniacal, and when only occasional oddities attract the observation of his friends or of his family, his Medical adviser finds the face partially flushed, but also partially pale, and sometimes moist. The general appearance of the countenance is distressful, and a sort of tension seems to prevail, as if no facial muscle was either quiescent or acting normally. Although there is a kind of lateral traction of the cheeks, the side face looks hollow, as if the cheeks had fallen in. The forehead is seldom calm, but usually drawn up into parallel furrows; the eyebrows are commonly raised into an arched shape, or, if not, are corrugated and depressed. The

yes express a singular blending of determination with fear, and with suspicion and indecision. They have also often an unnatural brilliancy, so that in dark eyes the pupils are scarcely distinguishable. In eyes of lighter colour, where the pupils can be distinctly seen, they are, I think, generally contracted. The eyeball seems often as if tensely pushed forward by muscular action. It seems, in truth, to be generally acted upon in varying thought. The mouth is scarcely ever natural in expression; the lips are compressed, or in a state of agitation, or open. The whole head is moved frequently and quickly, in obedience to the vagrant attention, or to fancied sounds and sights, towards which the ears and eyes are in quick succession directed. It is probable that the fibres of the muscles of the scalp are not quiescent; and in many cases the hair is remarkably acted upon,—straggling, wild, and dishevelled, or disordered in mental excitement; and falling densely and flatly over the ears and eyes of the melancholic. In the early stage of maniacal excitement, now chiefly referred to, the patient is restless; and sometimes the hands are bitten, or the fingers kept in the mouth during long-continued walking, within doors or without. Now and then transient gleams pass over the whole face, of sudden anger, or of hotly-conceived revenge,—reflections from a world of delusions or of dreams. Yet all these disfigurements, occasioned by mental excitement, are generally mitigated in the chronic forms of malady; and, what seems stranger, and is certainly more striking, begin to disappear in convalescence, and may be wholly dissolved when recovery takes place; so that the beauty of faces, long masked by disorder of the mind, is found to exist still, and to re-appear, almost surprisingly, when the disorder has passed away.

It is almost more miraculous to note in the face the delivery of a free mind from temporary melancholia—than which gloomy state nothing in this world is comparable for misery and distress;—a condition outwardly manifested in immovability, a fixed attitude and look, absence of facial muscular action, or slowly falling feet, lips compressed, or moving without sound: all disappearing when the reign of cheerfulness is restored.

Among the events most largely interesting to mankind, those associated with the succession of individuals to one another are among the most prominent. One of our finest moralists has dwelt strongly on the short and imperfect life of human beings, and its insufficiency for the perfection of the ever-advancing soul, as a corroborative argument for a belief in a future state. To this brevity of existence, however, man is indebted apparently for much energy that he might be less inclined to put quickly forth, if he could look forward to two or three hundred years for the accomplishment of the schemes he forms or the ambition he cherishes. But the rapid declension to which none are utterly blind makes the thoughts turn, in all men, with unusual interest to all that promises successors of their own blood, so as to support the proud belief that they may not altogether die out. The wonderful physical changes to which, in consequence of this arrangement, the frame of the female parent is subjected during pregnancy, and in confinement, and when furnishing the only food which is adapted to sustain the new life created in the creature new born, may naturally be supposed to put the whole female constitution to severe trial. The state of the brain becomes, in many instances, seriously affected by these changes, even physically; and, as may well be imagined, by the various emotions incidental to the months in which joy, hope, anxiety, suffering, and causes of debility, must, by turns, affect the whole system. Consequently, mental disturbance not unfrequently occurs in some stage of pregnancy, or soon after delivery, or during nursing. Before delivery, the uterus seems to show its constant influence over the female mental character, an influence never to be forgotten in practice, or disregarded, by capricious modifications, sometimes of small importance. But occasionally an apprehension of danger supervenes, or fancies become exaggerated, and there is actual mental disease. The form of malady which comes on during nursing is usually that of extreme depression.

The illustrations furnished by the admirable photographs of Dr. Diamond, and skillfully copied by the engraver, to accompany this discursive paper, present various forms of expression of face, incidental to puerperal insanity. The case thus beautifully portrayed was one of those which occasion much surprise, and even alarm, in an affectionate household. A young married woman has lately become a

mother; and for some days all goes on well. The father is conscious of increased importance; the nurse is proud of the baby, and seems to consider it almost her own. But this pleasant domestic state is all at once interrupted by the altered tone, or manner, or temper of the young mother; who speaks sharply to those about her, or loses her cheerfulness, becomes indifferent to her child, and seems as if her thoughts were occupied with scenes of gaiety, or in listening to amusing conversations; adopting a levity of manner and a fantastic arrangement of her head-dress or general apparel; and seeming to be detached from her husband, and from all about her, and from everything real. This is terrible in every rank of life; among the poor it is ruinous.

In the first of the four portraits of a case of this kind, there is represented a short initial stage of dulness and apathy. The patient was very quiet, and even sullen when addressed: she remained nearly all day in one posture, her hands crossed and resting on her knees, after the manner of melancholic patients; but the countenance, it will be seen, rather expresses bewilderment than unmixed depression; the eyes are directed forward; there is no very marked drawing down of the corner of the mouth or of the chin, and there is a slight elevation of the upper part of the cheeks; altogether, rather indicative of some advancing *mania*, more agreeable than talk, or even than food; and this patient was indeed not only sullen when spoken to, but refused food, partly, perhaps, because she feared to abandon the reverie.

There was, however, a depression mingled with her reveries, arising, as it would appear, from real circumstances. She had been an industrious woman, of good character; but she and her husband were poor, and, contemplating, probably, the difficulty of providing food, and clothes, and shelter for a coming family, her husband left her, and his home, and his country, to seek employment in Australia. The sensitive wife, whose mother had been insane, became deranged and melancholic, almost as soon as her poor little child came into the world of want, in which the father was so perplexed how to provide against starvation. But in a few days the memory of real events died away, and the malady assumed the form most generally seen after delivery. All the harassing troubles of life were forgotten, and husband and baby and her lonely home. The second portrait was taken eight days after the first. Her features were then not only lively, but cheerful: the mouth is drawn out laterally, the nostrils are expanded, and the lively eyes, the elevated eyebrows, and the merry cheeks and chin are felicitously rendered in the plate. She still sits with her hands crossed, and resting on her knee; but she looks as if she might easily be persuaded to get up and dance. She was, indeed, generally singing; she tore her clothes out of an excess of animal spirits; and she now took food, not only willingly but voraciously.

In about six weeks from the commencement of the malady, a great change took place, and recovery seemed to commence. She became quite comfortable, and was employed in needle-work; but had a somewhat impatient desire to go away from the asylum. At this time the third portrait was taken. She is seen standing up, and neatly dressed. Her face has lost its broad merriment; but there is a tension of the facial muscles, which prevents the experienced Physician from concluding that all the malady has yet passed away. Perfect muscular composure has not yet been established. In accordance with these prognostics, in a fortnight afterward she relapsed into the state of drollery and destructiveness portrayed in the second portrait. Happily, the relapse was only temporary, and in ten days more she was again industrious, and quite tranquil. From this time she remained so; and when her recovery was confirmed by a month of two more of observation, which the relapse had made advisable, she left the asylum quite well,—an event commemorated by the fourth portrait, wherein she is represented in bonnet and shawl, with composed features and pleasant honest face, animated still, but no longer excited; her general appearance indicating the restoration of the health and strength to be sufficiently called upon in the undertaking now meditated, of taking out her baby and rejoining her poor husband in Australia.

These four portraits were, I believe, the first attempts of Dr. Diamond to delineate, by photography, the progressive changes in the countenance in mental disease. They appear to me to be singularly valuable, even in an artistic point of view; and they certainly teach the medical observer more

forcibly than words. Repeated contemplation of them reveals several curious particularities which it is scarcely necessary to dwell upon. The disposition of the hair, dishevelled and starting away, as it were, from the head, in the first and second portrait; its quiet state in the third, and its neat arrangement in the fourth, illustrate observations already made. The somewhat wrinkled forehead, and the compressed eyebrows, in the first portrait, the uplifting of the frontal muscle and eyebrows in the second, may also be usefully compared by the medical student with the subsequent changes represented. After her voyage to the other side of the world, and at the joyful meeting of this poor family, it is to be hoped, therefore, that the recovered mother will carry back to her husband the face familiar to him in happier days—"the same face."

## ON THE USE OF METALLIC SUTURES AND METALLIC LIGATURES IN SURGICAL WOUNDS AND OPERATIONS.

By J. Y. SIMPSON, M.D.

Professor of Medicine and Midwifery in the University of Edinburgh;  
Physician-Accoucheur to the Queen in Scotland, &c. &c.

(Continued from page 574.)

### PART II.—RELATION OF LIVING STRUCTURES TO METALLIC AND ORGANIC FOREIGN BODIES.

IN pursuing the study of metallic as compared with organic surgical threads, there are two general laws in Surgical pathology which it seems necessary to consider before we can fully understand the relative advantages and disadvantages of these two forms of surgical sutures or ligatures. The two laws to which I allude have hitherto attracted very little attention from Surgeons. They refer to the comparative passiveness of living tissues to the presence and contact of metallic materials, and their excitability and irritation, on the other hand, under the presence and contact of foreign organic bodies derived from the vegetable or animal kingdoms.

#### LAW OF TOLERANCE OF LIVING STRUCTURES FOR THE PRESENCE OF FOREIGN METALLIC BODIES.

Metallic bodies, when lodged and imbedded without much mechanical contusion or injury in living tissues, produce comparatively little or no irritation by their presence; and if inflammation is excited by their contact, that inflammation is usually limited to the first or adhesive stage, and does not progress onwards to the higher stages or terminations of suppuration and ulceration.

In corroboration of this important general law, let me adduce some individual instances in evidence.

In the lower animals, when a portion of metal is placed in the subcutaneous tissues, and the external wound is closed over it, the foreign body becomes imbedded and fixed in its site, without leading to the production of suppuration and ulceration in the tissues in contact with it. With a view of testing this fact, I had placed deeply in the back and sides of a pig small pieces of gold, silver, copper, lead, and iron. We found no pus effused around these metallic bodies, when the wounds were opened and carefully examined six days subsequently. Around the pieces of gold, lead, and copper there was a thickish layer of coagulable lymph or fibrine, making as it were a complete cast of the foreign body; but showing under the microscope nothing but exudation corpuscles, and granules. Around the pieces of silver and iron there was no such distinct appearance of an incipient cyst (a); for the portions of metal seemed to be closely embraced by the surrounding tissues, with little or no adhesive exudation between their contiguous surfaces. In some experiments which Mr. Syme made several years ago upon the dog, with the view of ascertaining whether or not the periosteum could throw out bone upon its internal surface, he introduced between the radius and its periosteum a thin plate of metal, using, I believe, lead for the purpose; and the superficial parts were found to heal "kindly" over and around this foreign body, apparently without any tendency whatever to

suppuration or ulceration. . . . He exposed the radius in another experiment, cut away the periosteum, and surrounded the denuded bone with a piece of metal. At the end of six weeks he found a thick, rough capsule formed, enclosing the metallic plate (b).

But the law holds equally good, that metallic bodies may be lodged within the living tissues of the human body without creating any considerable amount of irritative reaction.

It is a well-known fact in military surgery that in gunshot wounds, after the immediate effects, in the way of contusion and injury, resulting from the mechanical force of the ball, have passed away, the metallic ball itself may lodge in the tissues of the body for months or years with impunity; more especially if the internal vital organs are not touched by it (c).

Since commencing these inquiries I have had reported to me, by my Medical and other friends, several instances in which bullets have remained lodged within the bodies of officers and soldiers still living, and who received them at Waterloo and in the Peninsular War, forty years ago, and upwards. One of the oldest and greatest of military surgeons, Ambrose Paré, when speaking on this subject, remarks:—"Lead Bullets (says he) lye in some parts of the body some whiles seaven, eight, or more yeares, so that they neither hinder the agglutination of the wound, neither doth any other symptome happen thereupon, as I have diverse times observed; untill at length by the strength of nature forcing them, and their proper weightines bearing them downwards, they shew themselves in some lower part, by their swelling or bunching forth, so that they must be taken forth by the hand of the Chirurgion. For they say Lead hath a certaine sympathy and familiarity with man's body, chiefly the fleshy parts thereof. Wherefore it neither putrefies it selfe nor causeth the flesh to putrefie; besides it hath an excellent faculty in cicatrizing old ulcers (d)."

To the same effect, in his essay on gunshot wounds, the celebrated John Hunter, when speaking of the practice of leaving the ball, and not dilating the gunshot wound on that account, observes, "This practice has arisen from experience; for it was found that balls, when obliged to be left, seldom or ever did any harm when at rest, and when not in a vital part; for balls have been known to lie in the body for years, and are often never found at all, and yet the person has found no inconvenience. This knowledge of the want of power in balls to promote inflammation when left in the body arose from the difficulty of finding them, or extracting them when found, and therefore in many cases they were obliged to leave them (e)."

It would be easy to adduce evidence of the same kind from the works of other and later Military Surgeons, as John Bell (f), Guthrie (g), B. Cooper (h), etc., but additional proof is perhaps superfluous, as the fact is one generally acknowledged in Surgical pathology.

Seeing thus that musket-balls may remain lodged without irritation or inconvenience, in contact with the structures of the living body, it is scarcely necessary to add,—what the experience of almost every Surgeon can corroborate,—that leaden pellets and small shot do often in the same way lie imbedded for years beneath the skin, or more deeply in the living structures.

In these cases of leaden bullets and pellets lodged for any length of time, the surrounding soft tissues, or a special cyst, embrace and hold firm the enclosed foreign body.

(b) Transactions of the Royal Society of Edinburgh for 1840, vol. xiv. p. 102.

(c) Sometimes, however, "balls (observes Professor Traill) have been lodged in various parts of the body, even in the chest, or the heart itself, for years, without causing death."—Outlines of Medical Jurisprudence, p. 87.

(d) English edition of Ambrose Paré's Works, p. 429.

(e) Hunter's Works by Palmer, vol. iii. p. 555.

(f) Discourse on the Nature and Cure of Wounds, p. 206. "A ball (says Mr. Bell) often lies without danger buried in the flesh for years or for life."

(g) Treatise on Gunshot Wounds, 1820. "When (Mr. Guthrie remarks) a ball has been lodged for years, we find that a membranous kind of sac is formed around it, which shuts it in as it were from all communication with the surrounding parts, and in some instances it seems to do so, and the patient suffers no sort of inconvenience from its retention."—P. 96.

(h) Principles and Practice of Surgery, p. 28. "It is not (Mr. Cooper observes) a matter of so much importance as might be supposed, that the ball should be extracted, as there are very many instances of persons in whom a ball has remained without producing any ill effect by its presence."

(a) In a later experiment I have seen a cyst formed around an angulated piece of bright steel.

"When (observes Mr. Guthrie) (i) a ball has been lodged for years, a membranous kind of sac is formed around it, which shuts it in, as it were, from all communication with the surrounding parts. If it should become necessary to extract a ball which has been lodged in this manner, the membranous sac will often be found to adhere so strongly to the ball that it cannot be got out without great difficulty, and sometimes not without cutting out a portion of the adhering sac." In an old patient, who had been affected more than once with syphilis, Morgagni found on dissection a leaden pistol-bullet, which had been lodged in his thigh thirty years before death. "There was," he adds, "a cyst or membranous follicle about that bullet, with which it was straightly inclosed all round" (k).

Flat pieces of lead may lie imbedded in the tissues of the human body, with apparently similar impunity to round bullets and pellets. Mr. Samuel Cooper quotes a remarkable example of this kind from M. Bordier, that happened at Pondicherry:—"An Indian soldier (says Mr. Cooper), angry with his wife, killed her and attempted to destroy himself, by giving himself a wound with a broad kind of dagger in the abdomen, so as to cause a protrusion of the bowels. A doctor of the country being sent for, dissected between the muscles and skin, and introduced a thin piece of lead, which kept up the bowels. The wound soon healed up, the lead having produced no inconvenience. The man was afterwards hanged, and M. Bordier, when the body was opened, assured himself more particularly of the fact" (l).

The instances which I have already cited refer only to lead, or lead and some of its alloys, lying in contact with the living tissues. And some authors, indeed, imagine that this negative property of harmlessness belongs, among the metals, to lead alone. "Bullets of stone (remarks Ambrose Paré) (m), Iron, and of any other metallic (than lead are of another nature, for they cannot remain any long time in the body without hurt; for iron will grow rusty, and so corrode the neighbouring bodies, and bring other malignant symptoms." But the evidence of other metals remaining harmlessly imbedded in living tissues, or passing harmlessly through them, is equally strong. Needles, for example, may, as is well known to Surgeons, long remain imbedded in the living tissues with little or no inconvenience. Even when they travel about from part to part from pressure of the muscles, etc. acting mechanically on one or other of their extremities, they produce little irritation in the course of their transit (n). "If foreign bodies, (says John Hunter) are such as can be made to change their situation by the action of the body upon them, such as pins or needles, or from gravity, as is the case sometimes with bullets, then the parts through which they pass seem not to be much altered or disturbed (o)."

Various other metals, or combinations of metals, besides lead and iron, possess the same negative property of harmlessness; and, indeed, this principle has been taken advantage of in the religious and other rites of some nations. Thus the Rev. Howard Malcolm, in his account of the religion of the Burmese, states: "Amulets and charms are worn by both sexes, but not by a large number, as among Hindus. One of these, common among military men, is the insertion of pieces of gold, or other metal, under the skin of the arm, between the elbow and shoulder. I was allowed," Mr. Malcolm adds, "by one of the Christians at Ava, to take from his arm several of these. They are of gold, inscribed with cabalistic letters" (p). Some of the Burmese warriors are, observes Captain Yule, in his late work on Burmah, said to retain the practice "of inserting a piece of metal under the flesh to make themselves invulnerable" (q).

Accident is frequently furnishing us with examples of the same law of tolerance of the living tissues for foreign metallic

bodies, and that under conditions where two metals are united. For instance, our common tinned iron pins often enough become accidentally lodged in the external tissues of the body, or are swallowed and even traverse different parts of the body without showing much irritation or inflammation along their tract. "In the cattle which feed in bleaching fields, there is not (observes Mr. Hunter) one of these killed without having their stomachs, etc. stuffed full of pins, and no seeming inconvenience takes place, for they appear to be healthy, and fatten as readily as other cattle" (r). Among "the cases that have occurred of persons swallowing pins, needles, etc. they have (says Mr. Hunter) been found to travel almost over the whole body, without producing any effect except in some situations exciting some sensations." Mr. Hunter, in the chapter from which I have made these quotations, is inclined to argue that the same material which will produce little or no irritation, or at the most only adhesive inflammation in the deeper parts of the body, will more and more readily induce suppuration as it approaches the external or cutaneous surface, "internal parts (to use his own words) assuming the suppurative inflammation more readily than the internal,"—p. 288. Hence he would expect an abscess to form around a bullet, pin, or needle lodged immediately beneath the skin, although the same bodies would excite no such inflammatory reaction when they were lodged in the deeper structures of the body. But suppuration does not by any means always, or indeed frequently attend the approach of metallic bodies to the surface; pins, needles, and bullets are often extracted by a slight incision through the skin, without a vestige of pus being traceable around them; and when they do, as, indeed, sometimes happens, lead to suppuration, when lodged superficially and subcutaneously, the inflammatory or suppurative action is generally, if not always, the result of compression and damage of the soft tissues lying around the foreign body, these soft tissues being, as the foreign body approaches the external surface, always liable to be contused and injured by every form of accidental outward pressure that impinges upon that surface. In fact, in the harmlessness of acupuncture needles, and, latterly, in the perfect innocuousness of metallic stitches, we have abundant evidence that metallic bodies produce, *per se*, as little irritation when lodged in the skin and mucous membrane, as they do when they are lodged in any of the deeper structures of the body. And, no doubt, Mr. Hunter was far more correct when he observed, "it is probable that these cases of pins, etc., owe their want of power in producing suppuration, not entirely to situation, but, in some degree, to the nature of the substance, METALS, perhaps, not having the power of irritation (inflammation) beyond the adhesive, for when the adhesive has taken place, the part appears to be satisfied" (s).

This great and important practical law of the tolerance of living structures for the presence and contact of pure metallic bodies has been fully expressed by an anonymous writer in the *Edinburgh Medical and Surgical Journal* for 1827 (t). The observations which this writer made thirty years ago are so apposite to the present inquiry, that I need make no apology for quoting them in full. "It is a remarkable circumstance (says he) that the acupuncture needles never cause inflammation in their neighbourhood. If they are rudely handled, or ruffled by the clothes of the patient, they may produce a little irritation; but if they are properly secured and protected, they may be left in the body for an indefinite length of time, without causing any of the effects which usually arise from the presence of foreign bodies. In one of M. Cloquet's patients they were left in the temples for eighteen days; and in cases in which needles have been swallowed, they have remained without causing inflammation for a much longer period. It appears probable, from the facts collected on the subject, that metallic bodies may remain imbedded in the animal tissues without being productive of injury; and that the property of irritating and inflaming by mechanical contact belongs only to those bodies which are non-conductors of electricity. But farther experiments are required to substantiate this curious and important law."

The author of the preceding paragraph, though right in his generalisation, is no doubt wrong in his explanation of the

facts. Other inorganic bodies, besides the metals, may be lodged with impunity in living tissues; and this, too, though they are non-conductors of electricity. Small pieces of glass, for example, occasionally remain long imbedded in the body in the same way as pieces of metal do. Mr. Hunter, indeed, points out this fact specially (u). A medical friend of mine has a small piece of glass imbedded in his lip, which has remained there with impunity for upwards of twelve years. I have heard of two or three cases of small pieces of glass lying quietly in the structures of the hand for long periods. An eminent surgeon had for twenty or more years a small piece of coal lying without inconvenience beneath the skin of the leg; and the small particles of carbon left by the explosion of gunpowder and by tattooing are well known to remain in the cutaneous tissues for a long lifetime without producing any irritation or disturbance. The Burmese, according to Mr. Malcolm, bury and carry not only gold, but also "sometimes small gems" under the skin of their arms (v). In fact, there seems to be a law of tolerance more general than the passiveness of living tissues to the presence in them of metallic bodies; this higher and more comprehensive law apparently being that living structures may endure with impunity the presence of inorganic, and even of dense organic materials, provided they are not porous and capable of absorbing and retaining within them the secretions which are thrown out around them.

Before closing these observations on the tolerance of living tissues for metallic bodies, let me add, that in this as in many other instances, when once a general principle is established, we often find that it will serve us as a clue to the explanation of facts of an equivocal character already alleged, but which from their very strangeness, and previous inexplicability, were still regarded with doubt by some minds. For example, we have already seen that one old mode of attempting the radical cure of inguinal hernia was by the "golden stitch," or by encircling the neck of the hernial sac with a permanent gold wire, which wire was left imbedded in situ, and the wound closed over it. The past history of surgery shows that this practice was followed as far as the safety and life of the patient were concerned, with a degree of frequency and impunity which was startling under our modern pathological ideas of the facility with which injuries and wounds of the peritoneum run on to dangerous degrees of inflammation and death (w). In the same way these ideas have again been upset in modern days by the new mode of radical cure for inguinal hernia introduced by Wurtzer, Rothmund, Spencer Wells, and other Surgeons, and which essentially consists in infibulating the hernial sac, and placing and keeping for several continuous days a stitch through this inverted portion of the peritoneal sac. We have proof of the innocuousness of this method of operating in the fact that Rothmund has, it appears, practised the operation now upwards of one thousand times without losing a patient, or seeing one case of fatal peritonitis excited by this prolonged puncture and transfixion of the peritoneum. In all probability the explanation of the comparative safety of both these modes of radical cure of hernia is simply this:—the thread or needle used is metallic, and hence, in accordance with the general law which we have been considering, inflammation is excited by the metallic thread or metallic pin only up to the degree or stage of adhesion. If a

silken thread is used for the purpose, then, as shown indeed by the result of Gerdy's experience upon the radical cure of inguinal hernia, the same operation comes to be attended by a higher and far more dangerous degree of inflammatory action (x).

#### LAW OF NON-TOLERANCE OF LIVING TISSUES FOR THE PRESENCE OF DEAD FOREIGN ORGANIC BODIES.

When foreign dead (y) organic bodies, belonging either to the animal or vegetable kingdom, are lodged or imbedded in the living tissues, they, as a general law, speedily produce morbid irritation and excitement, and a degree of inflammation which soon terminates in suppuration and ulceration.

In experiments upon the lower animals, pieces of lint-cloth, etc., lodged in the cellular tissue, etc., excite suppuration, inflammation, when portions of metal of equal size, lodged in their neighbourhood, and at the same depth excite only adhesive inflammation.

Foreign or dead organic substances are sometimes found lodging in and complicating wounds in the human subject, particularly gunshot wounds.

The walls of a gunshot wound along its tract through the soft tissues of the body are often to a greater or less extent killed by the force and blow of the ball, and consequently slough. Whenever a portion of soft tissue is in this way deprived of vitality, and becomes a dead organic substance, it excites in the contiguous living structures suppurative and ulcerative inflammation to such a degree as is necessary for the disjunction and elimination of the dead organic tissue.

When any portion of the soft tissue dies or sphacelates from any other cause, mechanical or morbid, it gives rise in the same way for its separation and removal to suppurative and ulcerative inflammation in the contiguous living structures.

The same law holds true in regard to a piece of dead or necrosed bone. Suppurative and ulcerative action is set up in the living tissues around it. When a piece or splinter of bone is struck completely off by a gunshot wound, the lodgment of this separated fragment of bone prevents, sometimes for a long period, the wound from closing, and keeps up constant morbid irritation and suppuration by its presence.

Pieces of cloth are occasionally lodged in the structures of the human body by gunshot wounds, the ball carrying before it and with it portions of dress, etc. The law of the non-tolerance of living tissues for the presence of foreign organic bodies, is strongly illustrated by the irritation and suppuration to which such imbedded portions of cloth give rise. The fact is one well known in military Surgery, and is alluded to by various authors. Thus, for example, Mr. John Bell, in his "Discourses upon Wounds," when treating of the circumstances which may impede the healing of a gunshot wound, specially points out, that, as a cause of its slow cure and of its continuous irritation and suppuration, "there may remain some foreign body within the wound; now," he continues, "a ball never produces these; a broken and corrupted bone would presently be known by the black colour and fetid smell of the discharge; and if the slow healing of the wound is known to proceed from neither of these causes, then most likely it arises from some piece of cloth which has passed in along with the ball" (z).

In the practice of his profession, the Surgeon often takes advantage of the same law; for when he wishes the sides of any artificial wound or opening which he has made not to adhere, he knows he can effect this purpose by lodging between the walls of the wound a piece of charpie, or other foreign body; and he is further certain, by maintaining the foreign body in this position for a few days, that suppuration in the walls of the wound will be excited by its presence.

A very small and minute fragment of dead animal or vegetable substance is sufficient, in accordance with this law, to excite suppuration in the living tissues among which it is lodged. Several years ago various eminent surgeons tried for a time the practice of cutting off both the ends of the ligatures with which they had tied vessels in amputations and other operations. The quantity of organic ligature required to be thus left buried in the closed wound around each deligated vessel

(u) Loc. cit. p. 288. After speaking of "metals perhaps not having the power of irritation beyond the adhesive," Mr. Hunter observes:—"This appears also to be the case with the introduction of glass, even in superficial parts: a piece of glass shall enter the skin just deep enough to bury itself; inflammation shall come on; the wound in the skin if brought together shall heal by the first intention; and the inflammation shall not exceed the adhesive, but rather degenerate into the disposition to form a sac, by which means a sac is formed around the glass, and no disturbance is given to the irritability of the parts. This was the case with Mr. Knight, Apothecary, who had a piece of glass three-fourths of an inch long run into the palm of his hand, and remained there for ten weeks, without any further inconvenience than retarding the motion of the hand, and sometimes giving a pricking pain when the sac was made to press upon the points of glass; this insensibility, however, arises from a sac being formed with such properties, but it cannot be assigned as a cause in the case of bodies moving as pins."

(v) Travels in Asia, vol. i. p. 307.

(w) In describing this old method for the radical cure of hernia, Purmann, for example, remarks, in reference to the frequency and comparative safety of the operation: "The famous and excellent operator at Leyden, Schmalzdus, was so expert at it, that you could perceive how he performed it without a diligent circumspection; yes, I verily believe, he could have cut fifteen patients in an hour's time, if he had so many. When I was there he cut but six in an hour, all which succeeded; but then he took more time than ordinary."—*Chirurgia Curiosa*, Book II. chap. 13, p. 161.

(x) See Mr. Spencer Wells's paper "On the Radical Cure of Inguinal Hernia," in the *Dublin Journal of Medical Science* for May 1858.

(y) We shall afterwards see that living organic bodies, as imbedded into, do not, while living, give rise by their presence to suppurative or ulcerative inflammation.

(z) Discourses on the Nature and Cure of Wounds, p. 203.

was extremely small. Mr. Lawrence calculated that the loop of silk thus left around each artery was, perhaps, not heavier than one-fiftieth of a grain; and the weight of flax or hemp thread required was not much more (aa). But though this vestige of foreign organic matter is not generally sufficient to prevent the union of the wound by the first intention, yet the practice has latterly been almost entirely given up by surgeons because they found that, as a general law, this minute fragment of organic ligature thus left imbedded in the wound became inclosed in a small abscess, and by its presence gave rise to a slow process of suppuration and ulceration, by which the ligature was ultimately carried out, and discharged from the surface of the body. "By some both ends (says Professor Miller) are cut away; in the belief that adhesion is thus favoured throughout the line of wound, as doubtless it is; and in the hope that the noose will become encysted, and give no further annoyance—as certainly will not happen. Adhesion under such circumstances is a misfortune; for the noose and its contained slough are to all intents and purposes foreign matter; as such their presence will be resented by the surrounding living textures; and as such they will be extruded by suppuration. Sooner or later—often after cure has apparently been completed—deep abscess forms painfully and slowly, having approached the surface, pus is discharged, and with it, its cause, the noose. Not until this latter has been put forth will the pain and discharge cease (bb).

Long organic ligatures of silk or thread, thrown around bleeding vessels, and left hanging out of surgical wounds, keep up in the same manner by their presence and contact a continuous process of suppuration along their tract; and at the point of deligation the tied artery is cut through by ulceration, before the ligature becomes separated and removed.

Organic sutures formed as suture-threads have hitherto been of silk, flax, or hemp, act in accordance with the same general law of the non-tolerance of living tissue for foreign organic substances, and when left for a short time, always at last excite suppuration and ulceration by their presence.

Indeed the common organic sutures hitherto used by Surgeons do thus so often prove noxious centres and sources of irritation in the lips of wounds as to have led, repeatedly, in the past history of surgery, to their more or less partial or complete rejection from practice. Above a century ago the published observations of Pibrac and Louis led, for a time, to the almost total discontinuance of sutures in closing and keeping in apposition the lips of wounds, whilst the same object was attempted to be obtained principally or entirely by the aid of position, plasters, and bandages. The best Surgeons of modern times, while returning again to the moderate use of silk and similar sutures, have very generally acknowledged the irritating and unhappy effects occasionally produced by them, particularly when too long detained. Thus the late Professor Samuel Cooper, in the last edition of a work that was long regarded as a standard exposition of English Surgery, remarks, that it must be allowed that the cause of some wounds not uniting, "is entirely ascribable to the irritation occasioned by the sutures themselves."

"Since (he observes) the sutures *always* act as extraneous bodies in the exciting more or less inflammation and suppuration round them, there can be no doubt that their employment is invariably wrong, whenever the sides of a wound can be maintained in contact by less irritating means, with equal steadiness and security. For what is it that generally counteracts the wishes of the Surgeon, and renders his attempts to make the opposite surfaces of wounds grow together unavailing? Is not the general cause too high a degree of inflammation, which necessarily ends in suppuration? Are not sutures likely to augment inflammation both by the additional wounds of the needles, and the still more pernicious irritation of the threads, which always act as foreign bodies, sometimes producing not merely an increase of the inflammation and suppuration in their tract, but frequently ulceration or sloughing of the parts; and, in particular constitutions, an extensive erysipelatous redness. More wounds are

hindered from uniting by sutures than such as are healed by them" (cc).

Or let me quote on this point the Author of the last work on Surgery published in this country:—

"Sutures (says Professor Pirrie) should not be employed when it is possible to maintain steady apposition without them. During the first day or two, and before they have cut their way by ulceration through the skin, they certainly act more powerfully than plasters in maintaining coaptation—one of the essentials for obtaining adhesion; but they also irritate much more, and, if not speedily removed, excite, at least in their immediate vicinity, sufficient inflammation to lead to ulceration, preparatory to their spontaneous extrusion, and the vascular action thus set up in one part of a wound, may extend so far as materially to interfere with or prevent adhesion. Even under the most favourable circumstances, a slight suppuration seldom fails to follow in the track of each stitch; and though, when the action stops here, the general healing of the wound may not be retarded, still the greater marking of the cicatrix, at each of these points, is an additional reason for avoiding their employment, when possible, especially on exposed parts (dd). Sutures, then (concludes Dr. Pirrie), are to be employed when there is difficulty in keeping the parts satisfactorily in contact by means of plasters; but they should be as few and far between as consists with the attainment of their immediate object."

In short, Professor Pirrie, like many other eminent Surgeons, holds with Mr. Hunter, that plasters have an advantage over stitches, by not inflaming the parts over which they are applied; "and (to use Mr. Hunter's own words) by neither producing in them suppuration or ulceration, which stitches always do." (P. 267.)

#### EXCEPTIONS TO THE TWO PRECEDING LAWS IN SURGICAL PATHOLOGY.

In pathology there are many general, but few or no universal laws. The two preceding general laws, like all other general laws in medicine, are liable to more or fewer exceptions, apparent or real. To understand the full practical value of these two laws or principles, let me here state one or two of the more important exceptions to them.

1. The presence of metallic bodies or threads is liable—like the presence of organic bodies or threads—to produce in living tissues absorption, with the formation of pus—or, in other words, suppuration and ulceration—provided it is combined with strong constriction of, or strong pressure upon these tissues. In fact, Surgeons have used, as we have already seen, metallic threads in this way, to produce by firm and forced constriction rapid ulcerative absorption in dividing the necks of polypi, or the solid walls of a fistula &c. &c. Here it might seem as if the metallic material excited by its presence, not adhesive, but suppurative and ulcerative inflammation. But this exception to the general law of the tolerance of living tissues for metallic bodies is more apparent than real. For the truth is that the resulting rapid absorption and absorption in these instances are the result of the more strong mechanical constriction and pressure of the living tissues, and quite independent of the agent or material, by which that constriction and pressure are produced. The effect would equally follow, whether the ligatures were organic or inorganic, provided only the physical amount of constriction and pressure made by them upon the involved living tissues were sufficient in degree. But the observation becomes important in another point of view. For it shows us that we must not expect metallic, any more than organic suture-threads, to remain quite free from any chances of suppuration and ulceration in their courses or tracks, provided they are so placed in a wound as to drag and press greatly upon the included tissues. The living tissues will only in general tolerate, without suppuration or ulceration, metallic threads, on the condition that they are so placed and so adjusted as not to produce unnecessarily strong tension and traction upon the structures through which they pass.

2. Though in surgery organic threads and ligatures, as a general law, speedily produce, by their presence, suppuration and ulceration in tissues in contact with them, yet there occasionally occur in practice exceptions, real or apparent, to

(aa) "A portion," says Mr. Lawrence, "sufficient to tie a large artery, when the ends are thus cut off, weighs between 1-50th and 1-60th of a grain; a similar portion of the thickest kind I have tried weighs 1-20th of a grain, and of the slenderest 1-100th. These ligatures do not interfere with the process of adhesion."—*Medico-Chirurgical Transactions*, vol. vi. p. 103.

(bb) Miller's Principles of Surgery, p. 362.

(cc) Cooper's Surgical Dictionary, Article "Sutures," p. 1811.

(dd) Principles and Practice of Surgery, by Professor Pirrie, of Aberdeen, p. 64.

this common principle in surgical pathology. Sometimes, though very rarely, an effusion of coagulable lymph only, and not of pus, is thrown out around the organic threads, or, in other words, its presence for five or six days, or longer, excites only adhesive, and not, as usual, suppurative and ulcerative inflammation. Again, sometimes another result is seen, viz. that when silk or flax threads and ligatures are left in the living structures for weeks or months, they in the first instance excite, as usual, more or less suppuration and ulceration in the tissues immediately in contact with them; but after a time the secretion of pus ceases, the included portion of thread becomes dried and rigid, like a non-porous, inorganic material, and subsequently becomes fixed in its site by effused coagulable lymph and granulations. I have repeatedly seen this series of changes in watching the effects of sutures in the lower animals; sometimes with one loop of suture thread remaining moist and the centre of a purulent collection, and a contiguous thread dried, stiffened, and fixed *in situ* by coagulable lymph and granulations. Similar examples occasionally occur in the human subject. Last year, in a case of complete and extensive laceration of the perineum, I brought the edges of the rent together an hour or two after delivery, by the usual deep quilled suture, and by some superficial stitches in the skin of the perineum, and the mucous surface of the vagina. Three days afterwards, the patient's Medical attendant removed the quilled suture, and the superficial cutaneous stitches; and the reunion of the parts was found complete. I did not see the patient from the day of operating, till three months afterwards, when I was asked to ascertain if there was anything wrong in the vagina. In the posterior wall of the vagina, in the site of the previous laceration, I found, still *in situ*, the two silk stitches, that had been used to bring the mucous walls of the rent into apposition, but which had escaped notice when the other threads were withdrawn. The embedded loops were dry and arid, and their sites marked by an accumulation of granulations.

Such exceptions, however, by their rarity only, prove the extent, and importance of the very law of which they thus form occasional variations.

(To be continued.)

## CASE OF PUERPERAL PERITONITIS,

TERMINATING IN THE FORMATION OF PELVIC ABSCESS

—RECOVERY.

BY HUGH CROSKERY, L.R.C.S.I.,

Late Assistant-Surgeon, R.N.

Charlotte Richards, a respectable coloured woman, aged 40, was attacked with Puerperal Peritonitis nine days after having given birth to her seventh child. When sent for two days afterwards, I found her in the following condition:—pulse 120, small, and unnaturally feeble; countenance expressive of great suffering; skin clammy; abdomen tense, swollen and excessively painful to the touch, especially over the right iliac region; milk scanty; urine high-coloured, and passed with difficulty; and the lochial discharge altogether arrested. The patient lay on her back, with her feet drawn up almost to the hips, and the slightest pressure over the abdomen could not be endured. As the time for the free and full use of the lancet had gone by, and leeches were not to be had, although I sent forty-five miles for them, the following treatment was adopted:—Flannels wrung out of hot water and sprinkled with turpentine were continually applied over the abdomen; ten grains of calomel and thirty grains of jalap were at once administered, and followed up two hours afterwards with a dose of compound infusion of senna; and after the bowels had been unloaded of a large quantity of offensive matter, three grains of calomel, and a third of a grain of opium were given every two hours. On the day following I found the symptoms very much mitigated. My patient had some sleep during the night, and was now lying on her side, which latter was in itself a good symptom; and the abdomen, although the pain was more diffused, was much less tender to the touch. I now ordered a blister the size of the hand to be placed over the right iliac region, and the blistered surface to be dressed with mild mercurial ointment; the calomel and opium to be continued, and the mixture as follows:—℞. carbonatis ammoniæ ʒi. spt. ætheris nit. ʒv., tinct., hyo-

scyami ʒii. mixturæ camphoræ ad uncias decem. misce et. ft. mistura; coch. mag. tertius horis. This treatment was persevered in for the next forty-eight hours; the patient had in the meantime intervals of comfortable repose, and when pytalism had been properly established, the abdominal tenderness ceased, the secretions became more natural, and there was, in fact, a relief to all the symptoms. She was ordered to continue the calomel and opium night and morning, but feeling herself so much better, she disobeyed orders, and discontinued it, and the consequence was, that the abdominal tenderness returned, and the disease assumed a chronic character. The mouth was again touched, hot fomentations were applied to the abdomen, and opiates given to relieve pain. A hard round tumour could be distinctly felt in the right iliac and hypogastric regions, and the least pressure in this situation caused excessive suffering. She made urine freely, and the passing of a catheter showed that there was no distention of the bladder. There was constant hiccup; the pulse was small, rapid, and feeble; skin clammy; tongue dry and furred; respiration hurried and thoracic; appetite bad. Three drachms each of tincture of opium and sulphuric æther were now added to her mixture, and besides this, she took about eight ounces of wine in arrowroot during the day. I was now convinced, from the firmness of the swelling before alluded to, its increasing size, and the absence of fever, that a pelvic abscess had formed, and I waited the result with some anxiety. My diagnosis turned out to be a correct one, for in the course of a fortnight—during which time the extreme torture from which she suffered was, to a certain extent, relieved by the exhibition of powerful opiates, and the application of soothing poultices over the seat of pain, and the sinking powers of life were sustained by stimulants administered every hour—the abscess burst somewhere into the large intestine, and large quantities of offensive purulent matter were discharged by stool. The greatest possible relief was now obtained, and she expressed herself as being comparatively free from pain. Enemata of lukewarm water were now given night and morning, a large opiate was ordered at bedtime, and the system was supported with beef-tea, ammonia, and wine. During the next four weeks, the drain on the system was enormous, as large quantities of purulent matter were almost daily passed by stool. During all this time she was actually kept alive by stimulants, and food of the most nutritious kind. Every day she had a pint of wine, half-a-dozen eggs beaten up with six ounces of brandy, a mixture of ammonia and sulphuric æther with decoction of bark; besides the most nutritious and easily assimilated food. Under this treatment the abdominal tenderness gradually disappeared, the purulent discharge gradually became less, and convalescence was slowly but surely established.

*Remarks.*—In the foregoing case, I cannot exactly state what was the predisposing cause, unless I ascribe it to previous disease; for she states that, in a former pregnancy she was similarly attacked, and that, having at once called in medical advice, she was bled and salivated. The disease was certainly not communicated by contagion, as this was altogether a sporadic case; nor was erysipelas, which is a kindred complaint, and capable of propagating the other, prevalent at the time. Atmospheric influence may, however, have contributed to its production; for in a system predisposed to it and prepared for it by a previous attack of a similar nature, a vitiated atmosphere, in an unhealthy and swampy district, would be, I should say, particularly conducive to the propagation of such a disease. My patient's house is built on a plain between the beds of two rivers, which ran on either side, and at this particular period of the year the water was low and almost stagnant.

## CASE OF PUERPERAL CONVULSIONS.

Harriet Harvey, aged 26, and the mother of three children, was attacked with puerperal convulsions on the morning of the 3rd of April, and in the sixth month of her fourth pregnancy. For some days previous her spirits had been very much depressed, and her bowels constipated; her face also and eyelids were full and dropsical. During her previous pregnancies she had been perfectly healthy, and she had not been subject to convulsions during either her virgin or puerperal state. I saw her six hours after she had been attacked, and during one of the paroxysms. Her face was swollen, livid, and terribly convulsed; her tongue was swollen,

lacerated, and protruded towards the right side; bloody froth issued from the mouth; the eyes were bloodshot and fixed, and the pupils dilated; the respiration partly stertorous, partly sibilant; and the pulse slow, full and labouring. I at once dashed cold water into the face, and the fit went off, leaving her in a state of apoplectic stupor. Before I had arrived, the fits came on every fifteen minutes, and with increasing severity. I saw that no time was to be lost, and, knowing that the lancet was my sheet-anchor, I at once opened a vein and allowed the blood to flow into a basin, until the breathing and pulse became soft and natural. After a time, however, the fits recurred, and the respiration became as stertorous as before. I had bled her the first time to the extent of thirty ounces, and two hours afterwards I took away twenty ounces more. Meanwhile, I had given an enema of tincture of assafoetida and oil in lukewarm water, and applied a sinapism to the nape of the neck. I had also put a bolus of calomel and croton oil on the back of her tongue, and had placed her feet and legs in warm water. The fits continued to recur, but with less severity, when, after a natural labour, and sixteen hours after she had been attacked, during which time she must have had, at least, sixty fits, the fetus was expelled. She now slept quietly for half an hour, when she had a strong paroxysm, induced, doubtless, by the presence of the placenta in the uterus, acting as a foreign body. I at once removed it, and the pulse became soft and natural, the stertor ceased, and she appeared as if in a calm and quiet sleep. I had now the benefit of the skilful advice of Mr. Laxton, of Old Harbour, who suggested that an opiate of forty drops of laudanum should be given by enema, and that a blister should be applied along the spine. I should mention that, during the fits, the pupil was fixed and widely dilated, and that, during the intervals, it was perfectly sensible to light. Forty-eight hours after the commencement of the attack, during which time my patient was in a state of complete coma, consciousness returned, and she recovered without a bad symptom.

Mullet Hall, Chapelton, Jamaica, April 8, 1858.

## THE LONDON PRACTICE OF MEDICINE AND SURGERY.

### HOSPITAL NOTES.

#### EXTRACTION BY THE LITHOTRITE OF A PORTION OF CATHETER FROM THE BLADDER.

Mr. Hilton has at present under his care in Guy's a man who, about a fortnight ago, happened the accident of breaking a catheter into his bladder. The instrument was a well-made, double-webbed, gum elastic, of No. 11 size. He had been accustomed to use it frequently, always employing a stilette. The reason why such an instrument should break does not appear clear, as there is no history of anything unusual having occurred. The man was admitted on the day of the accident, and brought with him the upper two-thirds of his instrument, which showed an obliquely fractured end. Mr. Hilton employed the lithotrite, and, having succeeded in laying hold of the fragment, withdrew, as was supposed, the whole of it. On measurement, however, it was found, that, although the portion got away, which was the last inch and a-half of the instrument, well fitted to the other, yet that it did not make up the whole length. On sounding again carefully, and using the stethoscope, Mr. Hilton succeeded in convincing himself that a third fragment still remained in the bladder. The lithotrite had no doubt cut the piece in two at the point of seizure. The man having had a severe rigor after the extraction (which was done under chloroform), no further attempts have as yet been made. Mr. Hilton proposes, however, in the course of a day or two, to again use the lithotrite. The bladder has been repeatedly injected, in the hope of displacing the fragment, and of favouring the chance of its spontaneous escape.

In connexion with the above, it may be interesting to mention, that Mr. Hilton stated in some clinical remarks, that he had had on the same day in private practice an almost parallel case. The subject of it was an elderly gentleman from the

country, for long a sufferer from urethral disease, and accustomed to employ a catheter. His instrument was a No. 11, and of gum-elastic, exactly resembling that of the Hospital patient, excepting that it was not so strong, having but a single web. The portion broken off was long, and was impacted in the urethra, but in such a manner that it allowed of the escape of the urine. It had been in that situation for several days before the gentleman was brought up to town. Mr. Hilton succeeded with a pair of long narrow bladed forceps in seizing the end of the fragment, and accomplished its withdrawal, having first with the finger in the rectum prevented its slipping further back.

The breaking of gutta-percha instruments into the bladder was, a few years ago during their extensive use, far from infrequent; but for well-made gum-elastic ones to break is decidedly rare. No doubt the large size in each of the above had much to do with the accident, since it would increase the tightness of the urethral grasp upon the terminal portion.

#### NECROSIS OF FRAGMENTS OF BONE IN CONNEXION WITH DISEASED JOINTS.

Mr. Solly has recently had two or three very interesting cases under his care in St. Thomas's, illustrating the occurrence of necrosis of portions of bone in connexion with diseased hip-joint. In one, a young woman, the portions were removed by operations, which consisted in the very free laying open of the sinuses, and examination of the parts. The head of the bone was dislocated. The exfoliated portions, which were quite loose, appeared to have belonged to the acetabulum rather than to the femur. The case had originally presented very acute symptoms. The whole of the exfoliated fragments having at length been got away, the girl made an excellent recovery. In a second case it was intended to make exploratory incisions, in the belief that some dead bone would be found; but it being discovered that the man was the subject of pulmonary phthisis, the idea was abandoned. The phthisis ran a rapid course, and an opportunity was soon afforded for a post-mortem dissection of the parts. The diagnosis was then fully confirmed, several portions of bone, which had no doubt been the main causes of the persistent irritation, being found. It is to be borne in mind that these cases are examples of the occurrence of necrosis, together with joint mischief, or rather, perhaps, as a consequence of it. There is another important group, in which the necrosis of limited portions of bone in the close neighbourhood of a joint stimulates mischief within its cavity. In the latter, a correct diagnosis of which is exceedingly important to perform, excision would be a blunder, while in the former, it would be justifiable, although not generally to be recommended, if there be reason to believe that the loose portions of bone are sufficient to account for the persistence of the disease, and that the original articular inflammation is tending to cure.

#### DILATATION TREATMENT OF OBSTRUCTIONS OF THE NASAL DUCT.

The plan of slitting up the lachrymal canal in order to gain access to the sac and nasal duct, as first practised by Mr. Bowman, is now very frequently followed in the out-patients' room at Moorfields, and with most satisfactory results. Formerly, in order to allow of catheterisation of the nasal duct, an incision had to be made into the sac, and risk was run that a fistula might remain. Besides this, it was a painful and very troublesome procedure, very disfiguring to the patient as long as the fistula remained open, and of course always leaving a permanent scar. The new plan is exceedingly simple, and avoids all these inconveniences. The lachrymal duct having been freely slit up on its conjunctival aspect, the introduction of a probe of any desirable size into the sac is quite easy, and when there, by elevating the handle, the nasal canal is readily entered. The slit-up duct remains permanently open, but without either disfiguring or inconveniencing the patient, and the surgeon may repeat the use of the probe at intervals for as long as may be necessary. We have seen several very threatening cases of lachrymal abscess wholly cured after two or three dilatations, but in a general way so few do not suffice. The intervals allowed should be from four days to a week, and the probe used should on each occasion be allowed to remain in for half an hour or so. The principle of cure is precisely similar to that of strictures of the urethra by the bougie.

## RECENT PREVALENCE OF TETANUS CASES.

To judge from our own impressions in visiting the different London Hospitals, we should suppose that tetanus has been most unusually frequent during the last few months. Seven fatal cases and one recovery have, we believe, happened in the London Hospital, within only a very recent period. At Guy's, at St. Thomas's, at St. Bartholomew's several cases have also occurred. At St. Mark's (for diseases of the rectum) there have been four fatal cases, in which the disease followed the ordinary operation of tying piles. An interesting case (traumatic) is still under Mr. Simon's care in St. Thomas's, in which recovery has ensued. Of this we hope before long to bring the details before the notice of our readers. Nicotine was, we are informed, the principal remedy used. A third case, in which recovery has taken place, is under care in Guy's.

## ABSCESS IN THE BRAIN FROM OBLITERATION OF THE CAROTID TRUNK BY THE PRESSURE OF A NASAL POLYPUS.

A pale, emaciated man, rather past middle age, was admitted, under Mr. Simon's care, into St. Thomas's on account of profuse bleeding from the nose. He was partially deaf. The left eye squinted inwards, and the right was totally blind, and had been so for some weeks. It appeared that so long as thirty years ago he had been under surgical treatment on account of a polypus in the nostril. Many attempts had from time to time been made to extract the growth, but had never been wholly successful. He was much reduced by loss of blood at the time of his admission, and a few days afterwards had an epileptiform seizure, which left him with incomplete hemiplegia of the left side. Ten days later another fit occurred, and death, in coma, followed thirteen hours afterwards. At the autopsy a very interesting and most unusual condition of things was found. In the right cerebral hemisphere were three distinct abscesses, and the brain substance generally was much softer than that of the opposite side. The cause of these was found in the entire obliteration of the internal carotid artery by the compression and irritation of a large nasal polypus, which had grown upwards and caused extensive absorption of the body of the sphenoid bone. It was impossible to trace the carotid artery through the cavernous sinus, its coats being inseparably blended with the dura mater and old inflammatory material. The sphenoidal sinus was occupied by a mucous polypus. There was not the least reason to consider the polypus of malignant nature, it being evidently of the ordinary fibrous kind. There were no secondary growths in any part of the body.

## THE ÉCRASEUR IN OVARIOTOMY.

In our number for Jan. 2, 1858, page 12, of the present volume, will be found the account of a case in which Mr. Spencer Wells proposed to use the écraseur in ovariectomy. In a successful case of ovariectomy, in February, at the Samaritan Hospital, Mr. Wells also intended to use this instrument, but was deterred by the size of the peduncle. The following paragraph, from the May number of the North American *Medico-Chirurgical Review*, proves the safety and advantage of the practice:—"Dr. John L. Atlee, of Lancaster, Pa., on the 23rd of March, removed a large multilocular ovarian tumour from a lady sixty-one years of age, by means of the écraseur. He cast the instrument around the pedicle, which was one inch in length by four in breadth, and highly vascular, and succeeded in removing it in six minutes and a half, without the loss of a drop of blood. The external wound was closed by silver sutures, and the woman made a rapid recovery."

## LIGATURE OF THE FEMORAL TRUNK ON ACCOUNT OF SECONDARY HÆMORRHAGE AFTER AMPUTATION.

In cases of hæmorrhage from a large artery in a stump, it is a question not always easy of answer whether the vessel should be resecured from the wound, or a ligature should be placed on the main trunk higher up. In a general way, to re-open the stump and tie the bleeding mouth, would no doubt be the preferable measure; but in certain exceptional cases, Mr. Guthrie's well-known rule on this matter may be judiciously deviated from. A very cachectic man, aged about 30, had his thigh amputated by Mr. Birkett, in Guy's, a few months ago, on account of a large fibro-sarcomatous tumour in the leg.

He did well afterwards, and the main ligature came away on the 16th day, all the others having previously done so. Two days after this, early one morning, profuse arterial hæmorrhage took place. The stump was now almost healed. In Mr. Birkett's absence, Mr. Bryant was summoned to the man's bedside. The bleeding had been very free, but was wholly arrested by the pressure on the femoral trunk, which the dresser was keeping up. An interval of about two hours now elapsed (pressure being persevered with meanwhile. The tendency to recurrence of bleeding on removing the hand, however, at length made Mr. Bryant determine not to wait longer; and having regard to the man's feeble and cachectic condition, and the probability that ulceration of the vessel had taken place, and that its coats were diseased, he decided to put a ligature on the common femoral. This was done with complete success. The man made a good recovery.

## WOUND OF THE FEMORAL ARTERY—UNUSUAL ARREST OF HÆMORRHAGE.

In connexion with the point of practice brought under debate by the above case, we cannot forbear mentioning very briefly one which has recently occurred in the practice of a Surgeon (Mr. Swales) at Sheerness. Although not an Hospital case, its interest will excuse our referring to it. A butcher's boy, aged 14, was swinging himself in the slaughter-house by a rope hanging from a rafter. By accident, he swung himself with considerable force on to the point of a large knife with which his master was employed at the other side of the room. The thigh which struck the knife was transfixed by it, and an enormous oblique gash on its inner aspect was inflicted. The bleeding was fearful, and the lad was at first believed to be dead. No doubt was felt but that the femoral trunk about its middle and several of its large branches were wounded. Feeling certain that more than one vessel in so large a wound must require ligature if the attempt were made according to rule, and fearing the results of a prolonged search and additional loss of blood in the already exsanguinated state of the patient, Mr. Swales determined at once to tie the common femoral. This was quickly done,—at least the armed needle was quickly passed under the trunk. On removing pressure, however, from the vessel after the ligature had been passed, it was found that no further hæmorrhage occurred. After waiting some time to see if it would return, and there being no reappearance, it was decided to leave the silk *in situ*, but not to tie it. For several days and nights assistants sat by the lad constantly in readiness to apply the finger and to tie the ligature should the bleeding recur. It never did, however; and at the tenth day the ligature silk was withdrawn. The boy made a good recovery, but at the time at which the particulars of the case were communicated to us, no pulsation had returned in the popliteal or tibial arteries. It thus seemed all but certain that the original diagnosis was correct as to the trunk having been involved in the wound. The arrest of hæmorrhage was no doubt due to the firm fixture of clots in the injured vessels during the long syncope which followed the accident. As to the wisdom of the daring omission to tie the ligature after it had been passed, the opinions of Surgeons will perhaps differ. Few will, however, dispute, but that the reasons which induced Mr. Swales to prefer tying the main trunk to exploring the wound were sound and sufficient.

## THE HOSPITAL PHARMACOPŒIA.

(Continued from p. 603.)

To pursue our illustrations of the practice of the Hospital for Skin Diseases, we may now advert to the subject of

**MEDICATED BATHS.**—The institution is provided with a good suite of bath-rooms, which are freely used. The pharmacopœia contains formulæ for the following:—"Balneum acidum," which contains an ounce and a half of strong nitric acid and one ounce of hydrochloric to thirty gallons of water. It is, we believe, but rarely ordered, being chiefly useful in cases of obstinate prurigo and lichen. The "balneum alkalinum," on the contrary, is the great favourite, and is prescribed twenty times for once of any of the others. It contains four ounces of carbonate of soda to thirty gallons of water, but is in a majority of cases used only half strength. Most patients suffering from inveterate scaly disease are directed to

Use this bath, twice in the week being the ordinary recommendation. The "balneum creosotii" contains two drachms of creosote and two ounces of glycerine to each bath, and is also mainly used against lepra and psoriasis. The "balneum gelatinii," which contains eight pounds of patent size dissolved in two gallons of boiling water, and the "balneum glycerinæ compositum," which has two ounces of glycerine and one of gum tragacanth in each bath, are mostly used for softening the skin in cases of congenital ichthyosis, or those milder forms of congenital roughness of the whole surface, which, although the same in kind, scarcely deserve that name. The disease is an incurable one, being a defect in structure; but we have seen many cases derive much benefit during the employment of one or other of these baths. Of the "balneum iodinii," and the "balneum mercuriale" we need not say more than that we believe they have no particular advantages over other modes (fumigation, etc.), of employing their active ingredients, while they are much more expensive, and that they are very rarely prescribed. There is in the Pharmacopœia a good formula for an artificial sea-water, under the name of "Balneum marinum." It may be useful to some of our readers in other affections, though very seldom called for in the treatment of skin diseases. The solution is made by dissolving eight pounds of sea or rock salt and two pounds of sulphate of magnesia in a pound of solution of chloride of lime and two gallons of water. The bath is made by adding a pint of this solution to thirty gallons of water. It would no doubt be very useful as a shower or sponge bath for delicate children, or as a douche in cases of chronic strumous swellings of joints, etc. There are very few skin diseases which sea-water or sea air suits, a point in practice on which Mr. Startin often insists, as the seaside is not at all an infrequent recommendation with some surgeons, and generally followed by much disappointment. A compound conium bath, at page 4 of the Pharmacopœia, contains, to every thirty gallons of water, a gallon of a fluid obtained by boiling together until dissolved, a pound of starch, and two ounces of extract of hemlock, in a gallon of water. We have now mentioned the whole of the formulæ for baths, excepting one, the "Balneum sulphuris compositum." This is made by dissolving four pounds of precipitated sulphur, a pound of the hyposulphite of soda, and two ounces of sulphuric acid in two gallons of water. Of this a pint added to thirty gallons of water makes the bath. In pauper practice, the sulphur ointment or lotion being cheaper than the bath, and infinitely less troublesome to the surgeon, will not be superseded by the latter. It is well, however, for the family practitioner to be armed with a formula for a less disagreeable and quicker plan for curing itch, should it chance to occur among his better-class patients. For this object the compound sulphur bath will be found very efficient. It might also with advantage take the place of the ointment in work-houses and other large pauper institutions, where this disagreeable disease is of frequent occurrence, and where it is very desirable to prevent the risk of its spreading.

(To be continued.)

**HORSE FLESH AS FOOD.**—It is said that the practice of eating horse flesh has of late years increased considerably in the north of Germany and Denmark. It is said that in the city of Hanover alone, in the course of Whitsun week, about 2000 lbs. of horse-flesh were consumed. The number of horses slaughtered for eating in that city is between 200 and 300 a year.

**THE CRYSTAL PALACE.**—The Crystal Palace at Sydenham is now presenting all its attractions to the metropolitan and provincial visitor. The flower show in May was highly successful, and it has been followed in the present week by a still more magnificent display of fruit and flowering plants—perhaps the finest ever seen in the Crystal Palace, or at any other metropolitan exhibition. The grounds of the palace are now in the very best condition; the rhododendrons and other American plants, the beds of flowers in the Terrace Gardens, and the vases filled with geraniums in full bloom, present a scene of beauty which is nowhere else accessible to the public. Any of our readers who would enjoy a day's fresh air amid all that can please the eye, charm the ear, and inform the mind would do well to devote their first holiday to a visit to Sydenham.

SATURDAY, JUNE 19.

### YELLOW FEVER AT ST. THOMAS'S.

By the arrival at Southampton, on the 17th ult., of the Royal Mail Steam Company's ship *Parana*, we learn that another outbreak of yellow fever, by far exceeding in severity any former visitation, has occurred at the island of St. Thomas's, so noted within the last ten years as being the centre of some of the most pestilential forms of disease with which any population has been visited in the past or present century. During the period of her coaling at St. Thomas's, and that of her homeward voyage, the *Parana* had seventeen cases of yellow fever, six of which were sent to the Hospital on shore, in all probability to meet the ordinary fate of almost all who go to that institution; and of the remaining eleven, three of the most able-bodied men of her crew, viz. the master-at-arms, the boatswain, and second engineer, fell victims to this fatal disease; and the fifth engineer was landed in a most pitiable state of prostration. Thus year after year, and month after month, we witness the arrival at Southampton of the Royal Mail Company's steamers, having lost of their crews on their return home numbers varying from five, ten, fifteen, and on one occasion about this time last year on board the same steamer, the *Parana*, no less than twenty-eight of that sturdy labouring class—the men who constitute the wealth of a community, and give it its power; and hence are the rightful claimants of its fostering care. The great importance, the vital magnitude of this subject demands the most searching investigation into the causes which give origin to such fearful and enormous calamities, and cry aloud for the protecting interference of the Directors of the Royal Mail Company and the British Government against so great and manifest an evil. In order to give any idea of the existing condition of the harbour of St. Thomas's, we beg to draw attention to some details on the subject, which, crude and imperfect as they appear, may, we trust, tend to the adoption of hygienic or governmental measures calculated to remove, to some extent, the baneful influences which so materially localise, aggravate, and propagate one of the most mysterious of diseases that flesh is heir to, and one which destroys so vast a number of the commercial and travelling community of this and other countries. The Island of St. Thomas's, one of the Virgin Islands, belongs to the Danes, and is situated in lat 18° 20' N., long. 66° W. Its population may be estimated at about 9000, of which 700 or 800 are whites, 2000 free blacks, and the rest are slaves. St. Thomas's has long been, and still continues to be, one of the principal emporiums in the West Indies. It owes this distinction partly to its spacious and safe harbour on the south side of the island, but principally to the moderation of its import duties. St. Thomas has, in consequence, become a *dépôt* for the supply of the neighbouring islands; and to this island the inter-colonial

ships of the Royal Mail Company resort, for the embarkation and disembarkation of their passengers and cargoes. The harbour is formed by a narrow inlet of the sea, and is a land-locked bay within, remarkably commodious as a station for shipping. On the right side of the entrance to the harbour, the town is constructed on the declivities of three hills; beyond these is the cemetery; and at the northern, or inland extremity of the bay are the negro huts, Gallows Hill, and Careen Hill. On the left of the entrance to the harbour is a lofty hill, or rock, on which a fort is built, and alongside of which are situated, at a considerable distance apart, two coal-wharfs, from whence the Company's ships take in their supply of fuel. This rock is connected with Careen Hill to which we have just referred, by a barrier of coral rock, called the Styx, thirty or forty feet wide, covered by one or two feet only of water, and across which the coal-people pass to the negro part of the town. The state of the water in this land-locked harbour may be easily inferred from the following description. The whole sewage of the town, the drainage from the cemetery, the torrents of excrementitious filth which descend after heavy rains from the ravines, on either side of which are squatted the 7000 or 8000 negro population, debouch into the bay with a force and velocity of which no one can form any conception who has not been an eye-witness to this lamentable state of matters. The Company's coaling station, situated towards the northern extremity of the rock referred to, at the left of the entrance to the harbour, consists of a wharf, from which run out three jetties, alongside which the steamers take in their coal from six or eight colliers, that almost encircle the vessel. The time occupied in coaling is about four days and nights, and the work is carried on by two or three hundred negroes, whose filthy habits may be more readily conceived than described. The calls of nature are dropped into the water under the jetties, and under the sides of the vessel. The *débris* of their food shares the same fate; and a repetition of a similar state of things takes place from the steamers, colliers, and every class of vessels which frequent the port. The hot sun and tides have alternate access to these putrifiable and offensive materials, and so concentrated is the noxious effluvia generated at and about the coal wharf and jetties, that it is painfully perceived at a considerable distance from the locality. Here, then, from week to week, every essential combination of deadly elements is found; for nothing is wanting to complete the ingredients for fostering and propagating an imported and most fatal pestilence. Indeed it would be difficult, if not impossible, to find a spot in any civilized country where there exists so gigantic and terrible a focus for the spread of disease as exists in the land-locked bay of St. Thomas's. Sanitary regulations and quarantine restrictions are wholly ignored by the authorities at this island, when an outbreak of yellow fever prevails; but for cholera and small-pox the most vexatious and absurd quarantine laws are imposed. As might be expected from a recital of the above circumstances, yellow fever is contracted at St. Thomas's, and thence carried to all the other West Indian Islands. On granting the bills of health, the form adopted by the authorities is, word for word, "that no plague, epidemic, cholera, *nor dangerous or contagious disorder exists in this island*;" but when ships from St. Thomas's visit the Island of Santa Cruz, forty miles to the southward, and the Danish seat of Government in the West Indies, they impose quarantine restrictions for yellow fever, and in the year 1857 absolutely refused vessels communication with that island! The only reply to inquiries made as to the reason for adopting such discordant views is, that to declare yellow fever an infectious or even a dangerous disorder would be to destroy the great emporium of their commercial enterprise.

The only remedies we can suggest are, first, that either the British Government should exert its influence with the

Danish authorities to remove or destroy, by blasting or by other means, the barrier of coral rock at the northern extremity of the harbour; or secondly, in the event of their not complying with such a suggestion, that the Royal Mail Company should abandon the island altogether, and by this means avert the fearful annual mortality occasioned by their selection of a harbour which may be characterised as the most foul pest-spot in any part of the habitable globe.

### THE WEEK.

Dr. Andrew Smith has resigned his appointment as Director-General of the Medical Department of the Army; and as failing health was the reason he assigned for wishing to retire, the Government were bound to accept the resignation. Now that the great services Dr. Smith has rendered to the State are becoming generally acknowledged, it is with no little satisfaction that we look back to the period when, amid attacks upon him from all sides, from both the general and Medical press, we made known how much Dr. Smith had done, and how much more he would have done had he not been thwarted by a faulty system and indifferent or incompetent ministers. Dr. Smith has remained at his post until the last sheets of the Medical history of the late war have passed through the press, and documents have been arranged for the information of his successors which will serve as most useful guides in any future war. A hard-working, clear-headed, thoroughly honest and kind-hearted man, he retires from the service with the best wishes of all that he may enjoy the leisure he has so well earned, and with the esteem and regard of all who know him—greatest of those who know him best. He is to be succeeded by Dr. Alexander, who won his spurs as principal Medical officer of the light division in the Crimea. It has not yet been decided how far the recommendation of the Sanitary Commission as to a Board of Officers to assist the Director-General will be adopted.

Professor Owen was elected on Monday Fullerman Professor of Physiology at the Royal Institution. The salary is about £100 per annum. The duties, the delivery of twelve lectures annually. The Chair is usually held for three years. The Institution, the Professor, and the Public, should all be well satisfied.

We announce with great pain and grief the death of our distinguished and estimable brother, Dr. Snow. He was suddenly seized with paralysis on Thursday, 10th instant, and died on Wednesday, the 16th, at his own residence, 18, Sackville-street, at 3 p.m. Drs. Murchison and Budd assiduously attended him to the last. Dr. Snow was only in his 46th year, and both on public and private grounds his early loss will be very greatly regretted. His name was known to the Profession chiefly in connexion with Chloroform, to which subject he had of late years devoted a great deal of attention, and next to Dr. Simpson he was more deservedly looked upon as the highest authority respecting the properties and administration of this agent. He had instituted at great labour a vast number of experiments for the purpose of ascertaining its effects on the lower animals, and the manner in which it might be given with the least amount of danger. His labours were fully appreciated by the Profession, and for several years the leading Surgeons in London constantly sought his co-operation. He was very successful in the administration of Chloroform, and we believe that only one death happened in his hands from this agent. Dr. Snow's labours were not by any means confined to this subject; he is well known as having devoted great attention to the investigation of Cholera, and his views regarding the propagation

of the disease by drinking impure water are familiar to the Profession. Dr. Snow was a man of high integrity and moral worth, possessing great abilities and untiring energy, with an unassuming disposition; and his loss will be deeply felt by many who appreciated his sterling character and valued his friendship.

Much attention being at present directed to the great mortality stated to have prevailed at one time among the household troops, it may be interesting to quote some facts illustrating that point from a communication recently published by Dr. Webster, F.R.S., which show conclusively, whatever occurred formerly, that since the Guards returned from the Crimea the total deaths recorded in the different battalions have proved inconsiderable. Thus, throughout 1856, although the London garrison usually averaged 3500 infantry, only 44 fatal cases by disease were reported from all the regiments. In 1857, the number fell to 29; while during the first three months of the current year, only 9 soldiers died in the military hospitals. These statistics, consequently, indicate that few similarly numerous bodies of men congregated together enjoy better bodily health than the military quartered in the metropolis; and therefore the conclusion enunciated by the writer just named seems well founded, viz.—“That many assertions now prevalent respecting the sanitary *status* of Her Majesty's Foot-Guards are greatly exaggerated, and not applicable to the present time.” On the contrary, according to the above statements, they must have been generally healthy, and hence their condition was lately very different from that characterizing 1839 to 1853 inclusive.

Sir Benjamin Brodie will be, in all probability, the new President of the Royal Society, as he has been recommended for election by the Council. The Profession may well feel proud at having so distinguished a member of our body placed at the head of the first of our scientific societies; and the gratification will be enhanced by the conviction that the honour is well deserved; for Sir Benjamin Brodie is not only our leading Surgeon, but he has shown that even his busy career has left sufficient leisure for the attainment of a high rank among men of science and philosophers.

While Mr. Tom Duncombe has been objecting to the destruction of Trafalgar-square by the statue of Jenner, his great discovery has been found necessary for the safety of our Indian Army. We have lost Peel from small-pox, and Dr. Tice has recommended the re-vaccination of the whole army. The camp followers are the chief victims, and the chief promulgators of the disease, because their religious scruples do not permit them to be protected by vaccination.

The eligible Fellows who are candidates for seats in the Council of the College of Surgeons at the ensuing election, on the 1st of July next, are Mr. Wormald and Mr. Quain, who retire from the Council in rotation, and Mr. Shaw, of the Middlesex Hospital, who has been nominated by Messrs. Paget, Busk, Charles Hawkins, Bowman, Hewett, and De Morgan. The election is by personal ballot—“ay” and “nay,” and not by balloting papers.

Very absurd notions have prevailed as to the income of the College of Physicians. The College has been talked of as poor, while the Elects, and other officers, were supposed to pocket large sums of money. This was the natural consequence of secrecy; but since Dr. Alderson has been Treasurer,

very full accounts have been rendered; and we are not now breaking any confidence in stating that the income derived from the private liberality and bequests of Physicians amounts in round numbers to £800 per annum, while the average amount of examination-fees does not exceed £600 per annum. Among the annual expenditure, about £300 goes to the poor and the Government in the form of rates and taxes, while the salaries of the officers are very small. The President has only seventy guineas, the Censors thirty-five guineas, the Treasurer fifty pounds, and the Registrar sixty guineas. Fellows, who are not office-bearers, receive nothing, and the whole remaining income is expended on the maintenance of the library and building, petty salaries, etc. It is true that the ground was presented by George IV., but the building was erected by private subscription. The Government has done nothing for the College, but tax every Licentiate £15, and every Fellow £25 on his admission.

We may direct attention to the questions given at the Oxford examination. They will be found in another column. Four candidates passed—Drs. E. Gray, A. Wallace, W. Ogle, and E. T. Wilson. The examination lasted three days. A large part of the practical examinations was conducted *vis à voce*, besides the clinical cases, which were described by the candidates at the Hospital. We have not printed the Classical Papers, but may say that the selections were particularly happy. It is probable that the period of study will be extended from three to five years, and that the examination will be divided into two periods,—one scientific and preliminary, for the M.B., without license to practice; the other for the M.D. degree, a practical examination, with the license.

Lord Granville, in addition to his statesmanlike qualities, is becoming a capital Chairman for a public dinner, if we may judge from his appearance last week at the Festival of the Medical Benevolent Fund. His allusions to the charity which distinguishes our profession, and to the abolition of the Property Qualification for Members of Parliament, which he had just been discussing in the House of Lords, and the good service which others than the most wealthy among us might render to the State in Parliament upon Sanitary questions, showed great tact, and the knowledge how to say the right thing at the right time in the right place and with the right manner. We have little more to say of the Festival, except that it was a very successful one, upwards of £800 having been raised, after some excellent speeches from Sir James Clark, Dr. Conolly, Mr. Probert, Mr. Toynbee, Mr. Erasmus Wilson, Mr. Squibb, Mr. Churchill, and other friends of the Charity. The presence of ladies in the gallery added greatly to the enjoyment of the evening; and we trust that if the practice of public dinners is to be kept up, it will become the practice for ladies to sit at the table, and take a more active share than they do now in the enjoyment of the feast. We throw out the hint for the benefit of enterprising committees,—gentlemen's tickets a guinea, ladies' half-a-guinea, would be an irresistible attraction.

“Frightful death from frightful Surgery,” is the apt heading of a fearful case recorded in the Jersey papers. The following is the verdict of the jury, and the evidence certainly leads to the conclusion that it is by no means too severe:—

“That the deceased died on Wednesday, the 9th June, 1858, from the opening of a vein whilst Charles Alexandre Désiré Hélie, styling himself Officier de Santé and Doctor, was performing the removal of the right breast of the deceased; and the members of the Inquest are of opinion

that, by his negligence in the performance of so hazardous an operation, and especially in operating without the assistance of Medical men, the said Hélie has rendered himself guilty of manslaughter, by imprudence and want of skill."

When we add that the deceased was in her 73rd year, that the excised part measured 11 inches by 9, and was 26 inches in circumference, that the poor woman's agony was not soothed by chloroform, that Hélie had no Medical assistant, and was engaged half an hour in his dire work, that the patient fainted and died after profuse bleeding, that the right subclavian vein was divided, the ribs laid bare, and that there was strong ground for believing that the pleural cavity had been opened; it is not too much to say that there is ample evidence both of gross ignorance and gross carelessness; still, it is but one more of the works of the "cancer curers."

Medical affairs have not been very prominent in Parliament this week. Lord Naas said he believed the report of the Lunatic Asylum Commission for Ireland would be ready by the 1st of July. Mr. Hardy said Government was desirous of getting rid of the bodies buried in the Metropolitan churches, but had not yet decided how to act. Some verbal amendments have been made in various clauses of the "Sale of Poisons" Bill. Lord John Manners was sorry the river Thames was not under his control, so that he could not diminish the stench arising from it. Next Tuesday Medical Reform is to be discussed at a morning sitting of the House of Commons; and we shall then see the effect the deputation of the Colleges has had upon Mr. Walpole.

We have received some communications respecting alleged consultations in the country between a London Hospital Physician and an Homœopathic practitioner. As the information has not been communicated to us by a gentleman who authorizes the publication of his name, we have not thought it right to publish the name of the Physician, but we have made inquiry as to the truth of the report, and find that this gentleman denies "ever having met in consultation any Homœopathic practitioners," but he saw a near connexion of his own, whose usual Medical attendant is an Homœopath, with whom he did not consult, but who saw the patient in the absence of the physician and carried out his wishes. This raises the question which, as we stated in a former article, ought to be discussed and settled. Where are we to draw the line between attending a case with and consulting with Homœopaths? The public do not see the distinction, and are apt to regard either course as a Professional sanction of the Quackery.

We have received a copy of a memorial of the Guardians of the Poor of the Wolverhampton Union to the Poor-law Board, which memorial, for cool impudence, surpasses anything of the kind we have ever seen. These sapient Dogberries, foreseeing that the reign of tyranny and oppression against the Poor-law Medical officers is likely soon to terminate by the energetic efforts of Mr. Griffin and others, who are now aided by the strongly expressed voice of public opinion, have expostulated with the Poor-law Board against any concessions in favour of the Medical profession. They are especially indignant at the idea of Medical officers of Unions having a Medical representative at the Poor-law Board, because, forsooth, such an appointment would destroy the "subordination" necessary for administering the Poor-laws! The Wolverhampton Guardians evidently regard their Medical officers in the same light as they do their porters, and they avowedly consider them on a level with the Workhouse masters; for, say they, "if a Medical advocate were placed

upon the Poor-law Board, we might have the spectacle of a Workhouse master's advocate sitting there too!" But when these persons go on to express their horror and dismay at the prospect of having also "a Union Clerks' advocate" at the Poor-law Board, surely their fears are groundless. Individuals even so obtuse as the Wolverhampton Guardians hardly require to be told that the whole Poor-law Board is composed of "Union Clerks' advocates;" for they are nearly all lawyers who sit at that Board, the exception being a few hungry placemen, who are quite satisfied to receive their salaries, and let the lawyers do the work. The argument that there is no dissatisfaction at Poor-law tyranny felt by the Profession, because new candidates are always ready to accept the vacant offices, is grossly and notoriously unsound, the fact being that in very many instances the leading Medical men of a district have declined to compete for Poor-law appointments, and the places have been given away to any persons who have condescended to accept them. But, while lamenting the want of union in our Profession, which, indeed, affords the only shadow of an argument offered by Poor-law Boards, we may ask,—if the Clerks of Unions were treated as Medical men are treated, namely, if they were underpaid and insulted, and dismissed at the caprice of their taskmasters, are there no lawyers dirty enough to accept the vacant places? But no; the "Union Clerks' advocates" are too strong at the Poor-law Board, and the Union Clerks are therefore universally well paid, never insulted, and, instead of being kept in a state of "subordination," are treated as gentlemen, and looked upon as advisers. There is nothing whatever in the education or the social position of Medical men which makes them inferior to Union Clerks; on the contrary, we should say that the inferiority is precisely the other way; and the only reason which can be discovered for the indignities to which our Profession has been subjected is the absence of Medical men in Parliament, and of a Medical advocate at the Whitehall Board. We shall, therefore, continue to urge the appointment of such a functionary, for the very reasons that the Wolverhampton Guardians, in their ignorance and arrogance, have thought proper to denounce it.

We have much pleasure in publishing the following Testimonial to Mr. Symes of Bridgewater, from his Medical brethren in that town. We have repeatedly expressed our opinion on the case, and we need only add that all the Medical men in Bridgewater signed the testimonial, with three exceptions, of whom, two having assisted the Guardians, and the third having issued a circular, intimating his desire to succeed Mr. Symes, should he be dismissed:—

"To HENRY SYMES, Esq., SURGEON, BRIDGEWATER.

"We, the undersigned, feel that the time has now arrived when we can without impropriety offer you the public assurance of our unfeigned sympathy and condolence upon the issue of your late struggle with the Poor-law Board. Having watched with much interest the progress of this struggle, we are in a position to say that the decision of the Board was contrary to fact; contrary to the evidence adduced; contrary to the feelings of your poor paupers, as set forth in their testimonial to you; contrary to public opinion, as evinced through the local and Medical press, and otherwise; and contrary to the opinion of the mass of your professional brethren. Englishmen hate oppression and wrong. And whilst we can vouch that your professional character will not suffer amongst Medical men under these harsh and intemperate proceedings against you, we entertain a well-grounded hope that a generous English public will incline to censure your persecutors rather than yourself. We beg to tender you our sincere and cordial sympathy, and our regret for the injustice inflicted upon you. (List of names attached to the Testimonial):—Reginald Burrigge, M.D., Taunton, Senior Physician to the Taunton Hospital, etc.; Henry Axford, M.R.C.S., Eng., Consulting Surgeon to the Bridgewater Infirmary; James

Haviland, M.R.C.S., Eng.; E. A. Stradling, M.R.C.S., Eng., Consulting Surgeon to the Bridgewater Infirmary; Robert Baker, M.R.C.S., Eng., etc.; Alfred Haviland, M.R.C.S., Eng., Surgeon to the Cannington Dispensary; Richard Axford, M.R.C.S., Eng., Surgeon to the Bridgewater Infirmary, and Medical Officer North ward district parish of Bridgewater; John Parsons, F.R.C.S., Eng., Surgeon to the Bridgewater Infirmary; Henry Long Jacob, M.R.C.S., Eng., etc.; Robt. R. Sewell, M.B. M.R.C.S., Eng., etc.; Horatio Nelson Tilsley, M.R.C.S., Eng., etc., Medical Officer North Petherton district Bridgewater Union."

### THE LATE SIR PHILIP CRAMPTON, BART., F.R.S.

Surgeon-General to the Forces, and Surgeon in Ordinary to the Queen in Ireland.

LAST week we briefly announced the death of the distinguished man who has for so many years held the foremost rank among Irish Surgeons, and whose name has so long been a household word with every lover of the science he adorned. Descended from a family who migrated from South Cottingham, Notts, and settled in Ireland in the reign of Charles the Second, and who have since furnished ornaments to each of the learned professions in that country, the subject of this sketch was born in Dublin, on the 7th of June, 1777. Having served an apprenticeship to the late Solomon Richards, Surgeon to the Meath Hospital, Mr. Crampton entered the army at an early age, and was present, as Staff Assistant-Surgeon, at the encounter with the French at Ballinamuck, in 1798; where he formed a friendship with the late Dr. Cheyne, which continued for many years, and was of essential service to the latter on his settling in Dublin some time subsequently. In the autumn of the same year young Mr. Crampton was, in his absence, appointed Surgeon to the Meath Hospital, an office which he held for the unusually lengthened period of sixty years, less by a few months. A singular circumstance attended his appointment, viz., that at the period of his election he was not legally qualified as a Surgeon. He had put in his first day's examination at the College of Surgeons with great credit; but during the time which was to elapse between the first and second examination he received his commission in the Army, and was required to join without delay. Immediately after his election to the Meath he passed his second day's examination, and became a licentiate of the College of Surgeons in Ireland. In 1800 he took the degree of M.D. in the University of Glasgow. He now commenced practice in Dame-street, whence he soon removed to Dawson-street. In November, 1804, he published "An Essay on the Entropion, or Inversion of the Eyelids." In addition to being one of the Surgeons of the Meath Hospital and County of Dublin Infirmary, he was now Assistant-Surgeon to the Westmoreland Lock Hospital, and had become a member of the College of Surgeons. Finding that practice flowed in but slowly, he commenced to lecture on Surgery, and was subsequently joined in the anatomical department by the late Peter Harkan. Thus was formed the first private school of Anatomy and Surgery in the City of Dublin. The *Dublin Medical and Physical Essays* published in 1807, contain additional observations by Mr. Crampton on Entropion. In the same volume we find an announcement that "Mr. Philip Crampton will commence his course of lectures on Anatomy, Physiology, Pathology, and Surgery, on Monday, the 29th day of October; Practical Anatomy, as usual, under the direction of Mr. Crampton and Mr. Harkan." From the time he commenced lecturing, Mr. Crampton's practice increased with surprising rapidity, and its augmentation was greatly hastened by a, for him, fortunate occurrence, which soon after took place. Opposite his house in Dawson-street was the Richmond Tavern, and it happened that a greedy waiter, in removing a dish, attempted to swallow a piece of meat, which, however, stuck in his throat, and he fell insensible on the floor. Mr. Crampton being hastily summoned, on the instant performed tracheotomy, and saved the man's life. The boldness, decision, and skill of the young Surgeon became the universal topic of conversation, and the subject of the highest commendation in the public papers. The results were, as the operator well deserved they should be, most satisfactory to himself. Mr. Crampton ceased to lecture

about the year 1812. In 1813 he published, in the *Annals of Philosophy*, "the description of an organ by which the eyes of birds are accommodated to the different distances of objects," which paper he illustrated with a plate representing the eye of the ostrich, so prepared as to exhibit the muscle of the cornea in its whole extent. We may give in the writer's own words, the manner in which he was led to the discovery of this organ, which is styled by Kolliker in his *Mikroskopische Anatomie* (Zweiter Band, pp. 634, 635, Leipzig, 1864) "der Cramptonsche Muskel," or "Musculus Cramptonianus." In an interesting "Outline of the History of Medicine," read before the Royal College of Surgeons in 1838, and published in the *Dublin Journal of Medical Science* (a), Mr. Crampton, having alluded to the discoveries of Scæmmering and Jacob, continues,—"Your reporter has been equally fortunate in discovering in the eyes of birds a distinct muscle arising from the inner surface of the bony hoop which surrounds the cornea, and terminating in a circular tendon which is connected with the internal lamina of the cornea. I was led to the discovery from the consideration that the faculty of adapting the refractive power of the eye to the different distances of objects, must exist in a higher degree in birds than in other animals. An eye, with a high degree of refractive power, is well adapted to the uses of the animal, while it rests upon the earth, but when it soars in the middle region of the air, the rays proceeding from the objects below must arrive at the eye in lines, which may be considered as parallel; consequently, to form anything like a distinct image, this refractive power must be lessened as the divergency of the rays decreases.

"It occurred to me, then, that if this change in the refractive power of the eye were effected by any mechanical contrivance, that contrivance would be, in all probability, more conspicuous in birds than in other animals.

"It was, therefore, with no common feelings of satisfaction, that I found in the eye of the ostrich and the eagle, and afterwards in all other birds, the mechanism for which I looked."

For this discovery, Mr. Crampton was honoured with the Fellowship of the Royal Society. About the same time, on the death of Mr. Stewart, he received from the Duke of Richmond the appointment of Surgeon-General to the Forces (b), on which occasion he resigned the Chief-Surgeoncy to the Lock Hospital, and early in the reign of George IV. he was appointed Surgeon-in-Ordinary to the King in Ireland. In 1815 he removed from Dawson-street to Merion-square, where he resided until his death. In 1839 he was raised by her present Majesty to the dignity of a Baronet of the United Kingdom, an honour which was at the same time conferred upon his former pupil, Sir Henry Marsh (c).

Sir Philip Crampton was always an ardent cultivator of zoological science, and took an active part in the formation of the Royal Zoological Society of Ireland, of which he has repeatedly been President. He has also on three or four occasions filled the office of President of the Royal College of Surgeons in Ireland. He was a member of the Senates of the University of London, and of the Queen's University in Ireland; a member of the Royal Irish Academy; of the Société de Chirurgie of Paris; of Guy's Hospital Surgical Society, etc. In addition to the appointments we have mentioned, he was Consulting Surgeon to Dr. Stevens' Hospital, and the Dublin Lying-in Hospital.

On the occasion of the completion of the fiftieth year of Sir Philip's Surgeoncy to the Meath Hospital, his colleagues placed a beautiful marble bust of him by Moore in the operating theatre of the Institution, as a tribute of respect to his high professional attainments.

(a) Vol. xiv., January 1839, p. 527.

(b) The office of Surgeon-General to the Forces in Ireland no longer exists, having been abolished in 1833.

(c) On the occasion of the inauguration of the new Medical College, at Stevens' Hospital, on the 27th October, 1867, Sir Henry in the opening address bore the following testimony to the Professional and private qualities of his distinguished preceptor. After having spoken of other Surgeons-General, Sir Henry Marsh added—"The present Surgeon-General (though this is not the Hospital to which he has specially devoted himself) has contributed not a little to the maintenance of its high surgical reputation. On all important occasions of operative Surgery he is to be found in the operating theatre, and always prompt and ready to lend his useful aid. He was once my master,—I had been his pupil. I obeyed his behests. Highly to this day do I value the surgical lessons I then learned from him. Greatly did I then, as I do now, admire his genius and his talents—great in the scientific world, as he is charming in his social and domestic relations."

In addition to the essays we have mentioned, Sir Philip contributed numerous papers to the Medical periodicals of the day. These may be found in the *Medico-Chirurgical Transactions*, the *Dublin Hospital Reports*, and the first and second series of the *Dublin Journal of Medical Science*. Among the principal communications not already enumerated are papers on Pericystitis, Obliteration of the Aorta, the Excision of Carious Joints, Injuries of the Head, Lithotomy, Lithotrixy, etc.

In a purely Medical and Surgical Journal it is, of course, chiefly with Sir Philip's professional character we have to deal. This notice would, however, be imperfect were we to pass over in total silence the kindness of disposition, the affectionate sympathy, particularly for those who, rich or poor, required his skilful aid, which endeared him to all classes; nor do we see why the testimony of one of his servants should not be recorded:—"I have lived with him for three and thirty years, and never did I hear a cross word from his lips."

Sir Philip was a remarkably handsome man even in his later days, so that there is probably some foundation for the following story, which has lately appeared in the *Press* of New York:—"George IV. visited Ireland in 1821, at which time Philip Crampton was Surgeon-General of the forces. He attended the King's levee, and wore the proper official uniform of his station, blue, with gold lace, epaulets, sword, and plumed cocked hat. This attire resembled that of a General of Artillery, and Crampton, who was over six feet high, and one of the handsomest men in Ireland at that time, looked remarkably well in it. His appearance struck the King, who made a remark to Lord Norbury, 'Fine man! General officer? in what branch of the service?' Norbury, who was a better courtier than to insinuate that royalty possibly could be mistaken, and too witty to sacrifice the opportunity of making a pun on Crampton's profession, answered, 'His name is Crampton, may it please your Majesty, and he is a General in the *Lancets*.'"

Sir Philip, during an unusually long period, held not only the first rank in his Profession, but enjoyed the highest consideration of society in general. Let it not be supposed that he attained this high position from fortuitous circumstances or incidental qualifications alone. Had his status been based on any such uncertain foundation, it could not have remained, not only unshaken, but if possible increasing in firmness to the last. On the contrary, originally endowed with great talent, and possessed of extreme activity of mind and body, he loved his profession ardently, and devoted his spare moments to its advancement. We have no doubt, too, that the principles of the higher order enforced in the following passages addressed by him to the pupils of the Meath Hospital class, in an introductory lecture delivered in 1836, with which we shall conclude this article, were those which mainly influenced his conduct in this respect:—

"You cannot but have perceived that in all that I have said respecting the danger to yourselves and others of neglecting, while you are yet young, to lay up a store of professional experience—of not postponing the study of your art until you are obliged to practise it as a profession,—you must have perceived that I have addressed myself to your selfishness generally, but especially to your selfish fears. I have said nothing of those higher motives, which it is to be hoped exert some influence on all minds, but which to some are the mainsprings of every action of their lives: my reason is, that, in addressing myself to men, I must make use of those motives which most generally determine their conduct. The question is not, what *ought* to make a man adopt such or such a course of conduct—we all know *that*; but what *will* make him adopt it.

"I wish to make you diligent in the pursuit of knowledge. I therefore place before your eyes the certain and immediate punishment which awaits idleness, rather than the remote, and perhaps less certain reward of diligence; besides, it is the peculiar and glorious attribute of virtue, 'that it is its own and great reward,' that those who are blessed with humane and generous feelings will exercise them,—must exercise them; and assuredly, if there be a field better fitted than another for the exercise of all those qualities, intellectual as well as moral, which most exalt our nature, that field is the province of medicine. To the Physician, beyond all men, is given the power of conferring on his fellow-man, and even the beings who are placed under his power, the greatest benefits and the

most supreme happiness. 'Walking himself in the valley of the shadow of death,' he is the means of dispensing life and health to others; and when he returns to the bosom of his family, loaded with the fruits of his honourable toil, yet still buoyant with the sense of success, his happiness will suffer no abatement, from the belief that, whatever may be that success, it is but 'the showing of a heavenly effect in an earthly actor (d).'"

Sir Philip died on the 10th of June, 1858, aged 81 years and three days. He succeeded in the baronetcy by his elder son, his Excellency Sir John Fiennes Crampton, K.C.B., Envoy Extraordinary, and Minister Plenipotentiary from Her Majesty to the Court at St. Petersburg.

The funeral took place on Monday. It was attended by numbers of nobility, the judges of the law courts, and of nearly all the eminent Medical practitioners of the city. There were also present a large number of Medical gentlemen from distant parts of the country, who came to pay the last tribute of respect to the memory of their master. By the directions given by the deceased some short time before his death, the body was placed in a solid Irish oak coffin without any lid; around this was placed a thick concrete of Roman cement, which was made to fill up all the spaces in the interior of the coffin not occupied by the body, which was covered over and entirely imbedded in the cement, of which nearly five hundred weight was used. This heavy mass was placed within another Irish oak coffin of great strength, on the lid of which was a shield bearing the following inscription:—

Sir Philip Crampton, Bart.,  
Died June 10th, 1858,  
Aged 81 years.

## UNIVERSITY OF OXFORD.

### EXAMINATION FOR THE DEGREE OF BACHELOR OF MEDICINE.

#### EXAMINERS.

Dr. ACLAND, Regius Professor of Medicine.  
Dr. CHAMBERS, Physician to St. Mary's Hospital, London.  
Dr. ROLLESTON, Lee's Reader in Anatomy.

#### No. I.

OXFORD, JUNE 1858.

#### Anatomy and Physiology.

1. Describe in the human subject the Bloodvessels at the base of the Brain,  
" at the Root of either Lung,  
" on the walls of the Oesophagus,  
" Stomach, and Duodenum,  
" in the Hilus of the Kidney.
2. State the origin, course, distribution, and functions of the Third Nerve in Man.
3. Describe a Typical Vertebra.
4. What are the several points of Ossification in the 1st, 2nd, and 3rd, Cervical Vertebrae? In the Scapula, Temporal, and Sphenoid Bones?
5. What conditions favour, retard, or prevent the Coagulation of the Blood?
6. What are the functions of the Cerebellum?
7. What effects are produced upon the several functions and upon the duration of Life by section of both Pneumogastric Nerves?
8. What are the objects under the microscope numbered i, ii, and iii?
9. State what you know of the accessions recently made to our knowledge of the physiology and minute anatomy of the Spinal Cord.
10. Describe the minute structure of the Human Lung.

#### No. II.

#### Chemistry and Botany.

1. Describe the several varieties of sugar; giving their sources in the animal and vegetable kingdoms, their employment in the arts, and the tests for their presence, together with such fallacies as these are liable to.

2. What are the Chemical constituents of the Urine, and what relation do they hold to the several tissues of the Body?

3. What is the received Chemical formula of each of the following substances—Ammonia, Cyanate of Ammonia, Urea, Uric Acid, Oxalic Acid, Creatine, Alloxan, Murexid, Albumen, Fibrin, Gelatin?

4. By what means do you recognise the presence of Arsenic in organic Solutions?

5. By what experiments has the constitution of the Atmosphere been determined with exactness?

6. Give an account of the methods in use for the determination of Nitrogen in an organic body.

7. How would you ascertain the absolute amount of Carbonic Acid present in a room of given dimensions? What is a proper cubical space for each patient in a Hospital ward?

8. What is meant by the terms 'Amide' and 'Nitrile'? Illustrate your answer by examples. Does Hydrocyanic Acid belong to either of these classes of bodies?

9. State the various processes by which Calomel may be converted into Corrosive Sublimate and Corrosive Sublimate into Calomel?

10. Describe the way in which plants are nourished, and name some substances which they seem to derive from the external world, and some which they elaborate themselves.

11. From what parts of what plants are derived (1) Opium, (2) *Extractum Colchici Aceticum*, (3) *Oleum Bergamottæ*, (4) *Rhei pulvis*, (5) *Tinctura Digitalis*, (6) *Strychnia*?

### No. III.

#### Pathological.

1. What is the state of the blood in patients affected with (1) Scurvy—(2) Anæmia—(3) Bright's disease of the kidneys—(4) Rheumatic fever—(5) Pleurisy—(6) Advanced pulmonary consumption—(7) Typhus—(8) Purpura?

2. Describe an ordinary case of confluent small-pox in an unvaccinated person.

3. What are the most usual chronic lesions after (1) Scarlatina—(2) Measles—(3) Ague—(4) Gonorrhœa—(5) Cholera—(6) Rheumatic fever—(7) Dysentery?

4. What may be the consequences of protracted exposure to cold and wet?

5. What are the poisonous effects on the human frame of (1) Mercury—(2) Lead—(3) Arsenic—(4) Digitalis—(5) Strychnia—(6) Tobacco—in large and small doses respectively?

6. Describe the invasion of illness, the course of the disease, and the post-mortem appearances in a child of ten years old affected with tubercles in the Arachnoid.

7. Name the urinary deposits under the microscopes A, B, and C.

8. Describe the post-mortem appearances most likely to be found in cases of Apoplexy, in the head as the immediate cause, and elsewhere as the remote causes of death.

9. What are the usual causes of chronic abscess of the liver?

10. Name forms of disease likely to affect bakers—cobblers—needle-pointers—stone-masons—well-sinkers—grocers—chimney-sweeps—lucifer-match-makers—and coal-whippers respectively.

### No. IV.

#### Therapeutical.

1. Describe the medical treatment of hæmorrhoids under various circumstances.

2. How would you treat the several complications of idiopathic low fever?

3. Are any rules of guidance for the administration of wine in fever to be obtained from the heart?

4. Describe the alkaline treatment of rheumatic fever, writing prescriptions in full without contractions.

5. What are the immediate effects of blood-letting, and under what circumstances would you employ it? By what tests would you judge of the power of the patient to bear it?

6. What is the physical action of heat applied externally to the human frame, and when and how would you employ it therapeutically?

7. If a woman during the early months of pregnancy lost blood *per vaginam* after unwonted exertion, what evil would you anticipate, and what means would you adopt to prevent that evil?

8. What prognosis would you give, and what treatment

would you adopt in a case of acute traumatic and chronic idiopathic Tetanus severally?

9. Write prescriptions for Elaterium, Scammony, Gamboge, Senna, and Rochelle Salt, intended to produce their full effect on an adult, 1st, simply, and 2ndly, in combination.

10. How did Rasori employ Antimony in inflammations? with what success? and with what risks?

11. How do cold moist air and warm dry air respectively affect the lung? and by what therapeutical means can you modify for a patient the hygrometric state of the respired air?

### No. V.

#### Clinical Examination. (*Radcliffe Infirmary.*)

1. Write a Clinical Report on the cases of whom you will find in

State the probable course of the cases, and write a brief commentary on them.

2. Are the specimens of Urine marked A, B, C, respectively healthy? if not, state in what particulars they are abnormal? If unhealthy, what indications for treatment do they furnish?

The Examination was concluded by translations from Latin and Greek into English.

## REVIEWS.

*A Manual of Obstetrics: Theoretical and Practical.* By W. TYLER SMITH, M.D., Physician Accoucheur to, and Lecturer on Midwifery at, St. Mary's Hospital. Pp. 628. London: 1858.

THE present manual, which is one of the series published by Mr. Churchill, will form a welcome addition to the many excellent treatises which have preceded it. A course of Lectures published in the columns of a contemporary forms the basis of the work; and in its present form it has been copiously illustrated with well-executed engravings in the usual finished style of Mr. Churchill's publications. With many of these illustrations we are acquainted in the pages of other obstetric authors, but many are original; and Dr. Tyler Smith frankly tells us in his Preface, that although he intended at first to give the authority for every woodcut taken from other works, yet that he subsequently abandoned the idea, from the difficulty of tracing the originals, but that he has himself added twenty new engravings to the common stock.

The importance of diffusing a sound knowledge of obstetrics appears to be amply proved by a reference to the statistics of mortality furnished by the reports of the Registrar-General. From these data, quoted by Dr. Tyler Smith, we find that about 3000 women per annum are destined to perish from child-birth in England and Wales; and this mortality refers to women in the prime of life, who, up to the time of labour, have enjoyed excellent health. These fearful results, it is justly remarked, are rather under than overrated, from the natural repugnance of practitioners to refer to child-bearing as a fatal process, and that the cause of death is truly returned (so far as it is possible) may be safely asserted when we mention that Dr. W. Farr is the authority upon the subject. Many of the deaths are no doubt due to the want of prompt Medical aid, and as many more to the meddlesome interference of ignorant midwives and other pretenders to obstetric science; but a great host of fatal cases are caused by the ravages of puerperal fever, the bane of parturient women, against which, when fully developed, the most consummate skill is of little avail. But, as Dr. Tyler Smith remarks, under a proper observance of hygienic measures, this destructive malady might be extirpated from the land, like typhus and other zymotic affections, which are gradually disappearing under the influence of preventive medicine.

To give an analysis of Dr. Tyler Smith's "Manual," would be to pass in review all the usual topics which are treated in midwifery lectures, and we must therefore limit our remarks to a few of the most prominent features in the work. The excitomotor functions of the uterus are carefully described, as might be expected from an author who has applied so successfully the principles of Dr. Marshall Hall's theory of reflex action to the reproductive organs of the female; and the periodicity of uterine action, whether in menstruation or in child-bearing, is

strongly insisted upon as a law in the economy. With respect to the existence of numerous nerves in the gravid uterus, Dr. Tyler Smith inclines to believe in the truth of Dr. Lee's views, and supposes that the discrepancies existing between Dr. Lee's dissections and those of Dr. Beck, may be due to the fact that the latter cleared away the neurilemma from the nerves, while the former dissected the neurilemma and the nerves together, as constituent parts of the same structure. The use of chloroform in labour is justified in all cases of obstetric operations and in other cases where the pains are unusually severe; but Dr. Tyler Smith states that he has had reason to believe that insanity has been sometimes caused by its too liberal use during labour, and that he has occasionally seen it suspend uterine action. He also informs us that some of the worst cases of laceration of the perineum which he has seen, occurred in patients under the influence of chloroform.

We have only to add that Dr. Tyler Smith has carefully consulted numerous authorities bearing upon the theory and practice of obstetrics, and that the precepts he lays down evince mature judgment and careful reflection.

*Medical Jurisprudence.* By A. S. TAYLOR, M.D. F.R.S. Sixth edition. London, 1858. 8vo. Pp. 976.

THE sale of five large editions of this work since its first appearance in 1843, is the best proof that some work on Medical Jurisprudence was wanted, and that this work has supplied the want. The present edition may be looked upon almost as a new work, not only because it exceeds in size by three hundred pages the first edition, but because the most recent improvements in Chemistry and Medical science generally, and the most important facts and cases bearing on Medical Jurisprudence which have been made known or discussed during the past fourteen years, have been collated by the author to make his manual, what we believe it to be, a thoroughly trustworthy guide both for lawyers and Medical men, upon all Medico-legal questions.

The sections on poisons, wounds, pregnancy and abortion, legitimacy, rape, asphyxia, insanity, indeed every subject treated, are illustrated by reference to the newest facts and most recent cases, and we can most cordially recommend the present edition, not only to those who have not, but to those who have, earlier editions.

*On Localized Galvanism applied to the Treatment of Paralysis and Muscular Contractions.* By R. M. LAWRENCE, M.D. London: 1858. 8vo, pp. 164.

IN a recent number of this Journal we published an interesting paper, by Dr. Lawrence, "On the Treatment of Hysterical Paralysis and Muscular Atrophy by Galvanism." In the work before us will be found chapters equally useful on other therapeutic applications of localized galvanism, especially in various forms of paralysis. The introductory chapters on animal electricity, the various electro-magnetic machines in use, the modes of applying the various forms of electricity, and the electro-physiology of the nerves and muscles, may be read with interest, and consulted with advantage, by all who wish to make themselves acquainted with the remedial powers of galvanism.

*Cosmos.* By A. VON HUMBOLDT. Translated under the superintendence of Major-General E. SABINE. Vol. iv. Part i. London: 1858. 8vo, pp. 616.

THE German original of this first part of Humboldt's fourth volume only appeared at the commencement of the present year. The appearance of the English version in so short a time could only have been secured by the cordial co-operation of author, editor, and translator; but it has been secured, and the English reader has presented to him in one connected and comprehensive treatise, a summary of what is known of terrestrial magnetism, and of the reaction of the interior of the earth or its exterior, including earthquakes, thermal springs, and volcanoes. It is a work which should be read by every educated man who would make himself acquainted with the results of observation on the great phenomena of the "World we live in."

## PROGRESS OF MEDICAL SCIENCE.

### Selections from Foreign Journals.

#### ON THE EMPLOYMENT OF THE THERMOMETER AT THE BEDSIDE.

By Professor WUNDERLICH.

THE object of Professor Wunderlich's paper is to call attention to the great value of this instrument in practical medicine, and to recommend its general employment. He says that he has some right to speak upon the subject, inasmuch as he has made in his clinique at least half a million exact thermometrical observations, and has followed the whole course of their maladies, and carefully compared the results in more than 5000 patients. He has also constantly employed the thermometer in private practice, and has continually pointed out to his pupils the practical character of the investigation. Some of the results have been published by his assistants or pupils in the *Archiv. für Physiol. Heilkunde*; and the principal conclusions have been summed up by himself, under the accounts of the respective diseases contained in his celebrated *Handbuch der Pathologie*.

Although by the aid of the thermometer we cannot at once arrive at any speculative idea of the nature of disease, yet are the facts it reveals fraught with the highest theoretical interest, and furnish important material for the solution of questions in pathological physiology. Surely there is motive for investigation, when it is found that the proper temperature of the human body can neither be materially diminished nor increased, without previous injury to its health having occurred. But in all degrees and kinds of muscular exertion or cerebral action, in every mode of respiration, in every degree of consumption or of loss, so long as the health is not injured—in every variety of bodily stature or constitution, at all ages and in all temperaments, and, indeed, in every condition of external circumstances, the temperature scarcely varies a degree. In the manifold varieties of disease considerable differences arise, sometimes almost suddenly, and sometimes only gradually; and even in the agony of death, when all the processes of life seem reduced to the lowest ebb, the temperature reaches its highest and most rapid elevation. Here we see a simple physical phenomenon, the entire purport of which can be exactly expressed in numbers, exhibiting, on the one hand, the greatest constancy under the most varied circumstances, and, on the other, numerous differences within narrow limits, and all limited by determined laws. Where in pathology, or in biology in general, can we indicate another equally favourable opportunity for obtaining an exact measure of concealed processes?

The practical worth of this means is immense, equalling that of any other mode of investigation, and surpassing most others even in local diseases, the participation of the entire economy being of the highest import. The practitioner who in pneumonia, peritonitis, typhus, etc., attaches all the importance to the changes undergone by the implicated organ, who regards it as scientific to attend only to the indications furnished by auscultation, microscopy, etc., and neglects all processes that are not capable of exhibition after death, will certainly regard changes in the temperature as accidental and immaterial. But the reaction against this mere local pathology is becoming stronger every day; and the conviction is firmly establishing itself that even for decision on the most localised affections, the appreciation of the general condition of the patient, of his strength and excitability, is essential, and that the question whether he has fever or not is of the highest import. And the facts acquired through the thermometer should convince the warmest advocate of localised action that the condition of fever entirely dominates over the development of local changes, the prognosis and the indication of treatment being frequently derived from it. The following are some of the examples of the utility of thermometrical observation:—

1. It is often of consequence to be able to quickly appreciate the importance of a recent change of health; and for this purpose the thermometer has no superior. If we find that the temperature remains normal, or nearly so, we can at once tranquillise the patient and his friends; for the disturbances (of course special cases, such as cholera, apoplexy,

hamoptysis, hernia, poisoning, etc., excepted) are of no significance, and need give rise to no anxiety. If, however, we observe a rise of two or more degrees, the advent of important disease is certain. This distinction is of great importance in children, in whom trifling ailments are often accompanied by disquieting symptoms.

2. The temperature will often alone detect latent but important disease. A mere indisposition, but attended with a considerable rise of temperature, is never to be made light of, marking as it usually does the beginning of important disease. A similar increase suffices to indicate the commencement of relapse after convalescence, or the advent of another form of disease. Exacerbation of temperature thus in typhus conveys most important warning. In intermittent fever there often occur one or more exacerbations of temperature, unaccompanied by any other symptom whatever. If we dissipate this by means of quinine, the patient recovers; but if this has been left off, we must expect a relapse.

3. In disease that has established itself the thermometer becomes the most certain basis of our diagnosis, the best corrective of a too hasty appreciation, and frequently the means of deciding in doubtful cases. Every one is aware that even in the best marked forms of disease, the diagnosis is still often difficult; and repeated experience has convinced the author that observation of the temperature is superior to all other means, and frequently at once solves the problem. To give an example: the course of the temperature, as exhibited in uncomplicated enteric typhus, is found in no other disease. Intestinal catarrh, some forms of pneumonia, intermittent fever with apparent continuance, meningitis and miliary granulations of the pia mater, acute tuberculosis, Bright's disease, or pyæmia, may simulate typhus; and may exhibit almost the whole of its characteristic symptoms: but observation with the thermometer will often at once, and at all events after a very few days, establish the distinction with certainty (Various other examples are given, for which we have not space).

4. Its practical application is not confined to mere nominal diagnosis. It is of more importance to be made aware of the intensity of a disease, and of its condition in respect to benignity or malignity. It is certainly of importance to be able to distinguish a typhus from a gastric catarrh, but it is not of less consequence to be able to distinguish, as soon as possible, a slight from a bad case of typhus. The difference between a pneumonia and a pulmonary catarrh is not of much more consequence than that between a mild and benign, or a severe and malignant inflammation of the lungs. A simple scarlatina bears almost more resemblance to a roseola than it does to a malignant scarlatina. And so in all cases, this determination of the intensity is for practical purposes, for prognosis, and for indications of treatment, of the greatest importance. There is no means of arriving at it more certain, more delicate, or more prompt, than the observation of the animal temperature. A great number of observations has taught the author to distinguish with certainty mild from severe typhus, amidst deceptive appearances, sometimes in the first week, but still oftener during the second; and to diagnose even in its earliest stages mild from severe pneumonia, benign from malignant scarlatina. The thermometer thus may often enable us to rest contented with expectative treatment, but at other times it indicates the prompt employment of energetic agents.

5. It is often of not less importance to determine the stage of the affection, that is, the point of development the internal changes have reached. This is especially the case in typhus, in which the internal exudation, a slow healing process, may by the inexperienced be regarded as a continuation of the disease, although it has other and peculiar dangers calling for peculiar treatment. By no other means than the observation of temperature, can we so exactly and so certainly appreciate these concealed processes.

6. In the course of many diseases, the diagnosis of which has been accurately established, additional developments, degenerations, or other complications may occur, which at first are often completely occult. The interruption of the course of the disease by a sudden rise of temperature, is the earliest and best indication of such occurrences.

7. The ordinary increase and aggravation of a disease are also by far the best ascertained by observation of the temperature. This will point out the occurrence of danger, and may indicate a positively fatal prognosis; for the advent of the

agony of death is in many cases foreshown by nothing so well as by a rapid and considerable change of temperature.

8. While a certain height of the thermometer ( $34^{\circ}$  R. or nearly) allows us to predict a fatal issue with certainty, and a considerable height (above  $32^{\circ}$  F.), is of bad augury, there are cases in which the observation of the temperature is the most favourable sign for the prognosis. Where we find in a bad case of typhus that it has fallen on some morning to  $30^{\circ}$  F., we know the reparative stage is entered upon; and when a similar declension is observed in the evening, convalescence has commenced. Evening declension in pneumonia shows the period of crisis has arrived. When the temperature falls in measles, the maximum of the eruption has been reached; and when, in the first stage of variola, we observe a quick return to the normal temperature, we may feel certain that a slight, dangerless form will ensue.

9. The temperature also indicates to us deviations in the curative process, which, together with their indications, would usually be concealed from us. The delayed deference in pneumonia, the continuation of a high evening temperature in typhus, or the exanthemata, the incomplete attainment of the normal temperature in apparent convalescence, are signs of the highest significance. They indicate incomplete recovery, supervention of other disease, unfavourable changes in exudation-products, or the continuance of chronic disturbance. The commencement of even a slight elevation of temperature during convalescence, is a warning to exercise careful watching over the patient, and for a due control over his diet and actions.

10. We may mention the enlargement of our knowledge of pathological phenomena as one of the most important acquisitions through thermometrical observation. This exhibits to us a regularity of type in the course of febrile affections, which is truly surprising. Our predecessors have, indeed, correctly suspected the existence of such typical courses, but have formulated it too hastily, and without sufficient material. The errors that have been committed have brought the doctrine into discredit, and the numerous observations made on mere local conditions have completely obscured it. To the thermometer the doctrine will owe its rehabilitation, placing it, as this will, upon the incontrovertible basis of observation.

11. When once the typical forms of the course of disease become established, the basis is laid for appreciating the irregularities in particular cases. These once indicated, we have to seek for their causes, and, when desirable, to prevent their occurrence. All irregularities are, however, not prejudicial, some being more favourable than the normal course of the disease, as in certain cases of irregular typhus or scarlatina. While, therefore, frequently the immediate object of therapeutics is the re-establishment of the typical regularity, it may be desirable in other cases to even induce certain irregularities by means of therapeutical procedures. In the one case, as in the other, the thermometer is the most correct, and almost the only guide.

12. In all the above instances their numerous relations to therapeutics are obvious. The thermometer indicates in many diseases that we may without anxiety resort to mere expectant treatment, and it points out the moment when energetic action should commence, and when the patient may again be left to the natural progress of his disease. It is also one of the most certain and delicate tests of the efficacy of the means employed. The contests as to the employment of bleeding and the administration of mercury, will only be definitively decided by the aid of numerous thermometrical observations. The utility of digitalis, antimony, camphor, etc., can best be learned from these; and all energetic procedures in febrile diseases should be submitted to the same test.

In all the above cases the determination of the temperature is the only exact means we have of measuring the processes of the general economy. For this it possesses the same value which auscultation, mensuration, and other modes of exact observation do for the appreciation of topical disturbances. It is of a higher practical worth, because in disease the indications for therapeutical procedures are derivable, with infinite more frequency, from the general condition of the patient than from those conditions which are termed topical, and the equalisation of which, little capable of being directly influenced, takes place for the most part spontaneously. The Professor, therefore, believes that he is not going too far when he states that the thermometer is indispensable for the exact observation of fever patients. Had we been accustomed to,

and properly appreciated its use, histories of disease, unaccompanied by continuous thermometrical observation, would seem as defective as would reports on diseases of the lungs, heart, spleen or liver without indications of the physical signs, affections of the brain, unaccompanied by accounts of psychical function, and maladies of the intestinal canal, in which no mention is made of the state of the alvine discharges. Perhaps some may complain of the institution of these observations is a new burthen, just as was said of the stethoscope and pleasmeter. But this must be got over, and the time is not distant when no Physician will venture to pronounce upon a febrile disease without the application of the thermometer, or in the milder cases the employment of a hand, well exercised by numerous comparative observations, as an approximative means.—*Archiv. für Physiol. Heilkunde, Neue Folge*, b. i. pp. 6—16.

## GENERAL CORRESPONDENCE.

### VACCINATION IN IRELAND.

LETTER FROM J. J. TRAYER, M.B., T.C.D.

[To the Editor of the Medical Times and Gazette.]

SIR,—Many reasons might be assigned for the great falling off in the amount of vaccination performed by the Poor-law Medical officers of Ireland within the last few years. Perhaps it might have a beneficial effect were individual practitioners to state distinctly the causes which they have felt and known to be in operation in their several districts. Permit me then to call attention to one which I know to be fruitful in checking this most important practice. Formerly the Poor-law vaccinators were permitted to enforce and secure the return, on the eighth day, of parties whose children they had vaccinated by taking a small pledge in the shape of some trifling article of dress, or a small coin, which pledge being duly marked with the name of depositor was returned on their re-appearance at the proper time with the vaccinated child. This practice is now expressly forbidden by the Poor-law Commissioners, and the consequence is, that it is now quite exceptional to obtain the return of such parties, and recourse is obliged to be had again and again to the dry lymph obtained from the Vaccine Institution. It is plain that no matter how carefully preserved the lymph be, no matter how skilfully the vaccination with it be performed, it is by no means so certain in its effects as the fresh lymph. Moreover, the supply sent usually is of but limited extent, seldom for more than three or four children, and thus parties are disappointed, take offence, and fail to apply again for months or years. Again, with a few exceptions, the fresh lymph is very much preferred by the parents who, when they see "a nice poek" on a "clean skinned healthy child" in their neighbourhood, flock in to secure the advantages of vaccination, without incurring the risk—fancied or real, but very commonly believed in in Ireland at least—of some blood contamination being communicated with lymph obtained from some unknown, and therefore suspected source.

What may be the reasons that influenced the Poor-law Commissioners in putting an end to so convenient a practice, it is not for me to imagine. If it were any dread that such a proceeding interfered with the freedom with which parties sought gratuitous vaccination at the dispensaries, I can safely say that such a fear was groundless. This little pawn-broking interlude was, in my experience, a source of no unpleasant feeling, often the occasion of a little friendly banter, that relieved the sameness of dispensary work, without seriously injuring the dignity of the local Hippocrates, and was so successful in attaining the desired object, that I only remember one pledge having been left on my hands. The steady maintenance of a supply of fresh vaccine was not the sole, though the chief advantage of this proceeding; by it every case was brought once at least under the Medical officer's eye, and that on the day when the cow-poek presents its most characteristic phase, and thus some definite idea was obtained of the result of the operation. I am sorry to say that in this neighbourhood, though not in my own district, the worst anticipations of the Commissioners are being realized as to the prevalence of variola in an epidemic form at least. I hear a great deal of its great frequency, and have reason to

fear that the inoculators are driving hard their nefarious trade. Secure a fair average return of the vaccinated children to the dispensary, and you will have a steady supply of children to vaccinate, and thus, for variola and its most accursed propagators, you do all human means can do to spoil the market.

I am, &c.

J. J. TRAYER, M.B., T.C.D.

Bagnalstown, Co. Carlow.

## HOMOEOPATHY.

LETTER FROM T. H. BARKER, M.D.

[To the Editor of the Medical Times and Gazette.]

SIR,—It would appear that the Homeopaths vince under the Bedford Resolutions. This morning I received the following note from Dr. Eppe, which, with the short reply, I forward to you, in order that your readers may be upon their guard.

I am, &c.

T. HERBERT BARKER.

Bedford, June 10. 1858.

[COPY.]

89, Great Russell-street, W.C.,

June 8th, 1858.

SIR,—I find your name in connexion with a meeting at Bedford on the 21st of May. I find thereat certain resolutions passed unanimously. I need not designate these resolutions.

Engaged in writing a history of Homoeopathy, which, I trust, will be, years hence, regarded as a standard work, I shall chronicle the facts, illustrative of the opposition Homoeopathy met with, and shall try to impart a knowledge, not simply of the general character of the opposition, but by recording both the names and the status of all the parties who publicly joined in that opposition, and the modes under which that opposition took form, thereby rendering more tangible to the recognition of those who come after, the reality, and the special character of the opposition.

To render the history perfectly truthful and just, I have felt bound, wishing to do to others what I would wish others to do to me, to try and ascertain before recording your name as one of the units engaged in the opposition, whether or not you gave your sanction to the resolutions referred to.

Believe me, with best wishes,

Sincerely yours,

JOHN EPPE, M.D.

[COPY.]

Bedford, June 10, 1858.

DEAR SIR,—In reply to your note of the 8th inst., received this morning, I beg to say that the resolutions referred to received my most hearty sanction.

I am, dear Sir, yours most faithfully,

T. HERBERT BARKER, M.D.

Dr. John Eppe.

## MEDICINE AND THE STATE.

LETTER FROM RICHARD GRIFFIN, Esq.

[To the Editor of the Medical Times and Gazette.]

SIR,—I shall feel obliged if you will favour me with space to address the Poor-law Medical officers on subjects deeply affecting their interests.

The reply of the President of the Poor-law Board to Mr. Booth, in the House of Commons, on June 10th, is most important, as it proves that our past labours are now in a fair way to meet their reward; still we must continue to be vigilant, as dangers beset our path; e.g.:—Recently the Wolverhampton Board of Guardians have drawn up a memorial containing a tissue of misstatements, which they have presented to the Poor-law Board, and pray "that they will refuse to accede to the wishes expressed by the deputations of Medical officers." Not content with this, they have also appealed to all other Unions for co-operation.

The Bill for a superannuation fund for Poor-law officers, issued by a committee in London, composed of 9 masters of workhouses, 14 relieving officers, and 10 clerks to

Boards of Guardians, requires our serious consideration, as by it a deduction from the salaries of all officers, Medical included, of 2½ per cent. is to be made compulsory. In its present state I feel confident the proposed Bill cannot be worked, and will not give satisfaction to the Medical officers; a copy will be found in Knight's Official Advertiser, which is sent to the clerk of each Union.

The "Friendly Societies Bill" now before the House, compelling a gratuitous Medical certificate in case of death, is unjust to the Poor-law Medical officers, to whom it alone applies, and ought to be opposed.

The Vaccination Bill about to be introduced, will require to be narrowly watched, lest we be offered an indignity similar to that which is threatened to be imposed upon our Irish brethren—"sixpence per case for successful vaccination!" Could the illustrious Jenner rise from his tomb, would not he be astounded at the niggard value set upon his immortal discovery? Better far that we should vaccinate gratuitously, than accept so paltry a payment.

To be successful in our efforts to improve our position requires unity of action, and ample means at command, without which our best endeavours may be unavailing. Some gentlemen have contributed most liberally to the Association Fund, but a vast number have done very little, and many literally nothing. Since the commencement of this year, 593 Medical officers only out of the 3200 have sent subscriptions. This apathy is unworthy a noble Profession, with so much at stake. For years past the Poor-law Medical Department has been in a degraded position, ground down to so low an ebb that resignations have been most numerous, almost compulsory, 29 having taken place during the last month. Surely, now there is a prospect of making ourselves respected by the Guardians, and the community at large, my friends will awake from their lethargy, and prepare themselves to support the proposed Bill of the President of the Poor-law Board, or to press upon Parliament the necessity of its amendment, should such be needed; and also to take their share in the support or rejection of the other Bills; but this cannot be done without funds—printing on an extensive scale, and a large and continuous correspondence being absolutely necessary. Surely a few shillings from each member cannot be considered thrown away in an attempt to redress the wrongs of our oppressed brethren—omitting altogether the prospect of obtaining the £231,000 mentioned by Sir John Trollope, or even the 50 per cent. named by the President, which is £115,000 annual addition to our salaries.

I am, &c. RICHARD GRIFFIN.

12, Royal Terrace, Weymouth, June 14, 1858.

## CONSTANT GALVANIC CURRENT.

LETTER FROM MR. ROBERT REMAK.

[To the Editor of the Medical Times and Gazette.]

SIR,—I feel very much astonished and dissatisfied that the short communication, which you kindly inserted in your valuable journal of the 8th of May, and by which I intended merely to draw the attention of Physicians to some therapeutical effects of the constant galvanic current, should have excited one of our colleagues to make so hostile a reply, as is to be found in the letter of Dr. J. Althaus, contained in the *Medical Times and Gazette* of May 15.

1. Dr. Althaus thinks that the assertions made by me upon the subject do not even deserve an answer, because I have said in my paper "that the current of induction cannot be applied to the living body without shocks, and that these shocks have a weakening effect." I am not at all astonished that this assertion should appear inconceivable and incredible to Dr. Althaus and other electricians; "but for the physical" and physiological explanation of it, I can confidently refer to the papers quoted in my communication, or to my work now in the press.

2. Dr. Althaus supposes he supports the unfavourable opinion which he endeavours to diffuse, by quoting some expressions of the Editor of the *Gazette Hebdomadaire*, made two years ago, after having witnessed the experiments made by me in Paris on some patients. I will not at all deny the impartiality of Dr. Déchambre; but practitioners will conceive, that even were results negative in four cases under observation (before my method was developed), the value of the

remedy cannot be affected by this circumstance, after the results obtained now in 750 cases.

3. It is stated that "my discovery was made and applied a long time before by Nobili, Matteudore, and Bequerel." The history of the practical application of galvanism (which will be given in my work) can alone prove that this is incorrect.

4. Dr. Althaus says that, according to my assertions, "the current is one of the most wonderful agents that has ever been heard of." I can only, for my part, repeat that I have conscientiously given my results, and that I expect to find them corroborated in the future.

Finally, Sir, permit me to observe, in regard to the mark of interrogation, which you have made at the end of my sentence "upon the inflammatory states of the spinal marrow, which sometimes precede atrophy of this organ," that Rokitsky has recently published a very excellent memoir upon this subject, in the Reports of the Academy of Sciences of Vienna. I am, &c.

ROBERT REMAK.

141b, Friedrichstrasse, Berlin, June 9, 1858.

## REPORTS OF SOCIETIES.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MAY 25, 1858.

Sir C. Locock, Bart. President, in the chair.

(Continued from page 614.)

Mr. Birkett read a paper on

#### A CASE OF FIBROUS POLYPUS OF THE URINARY BLADDER, WITH OBSERVATIONS.

The new growths developed in the bladder may be thus described:—

1. Papilloma.
2. Fibrous Polypus.
3. Villous growths.
4. Epithelioma.
5. Carcinoma, and Infiltrating, and Tuberculous.

It is upon the second class that the author desired to concentrate attention. This growth resembles in every anatomical particular the "nasal polypus," which is the true type of the disease. These growths occur very rarely, and the author can find only ten cases, the description of which accords with that about to be given. Warner, Baillie, Walter, Crosse, Savory, Chopart, and Petit, each relate a case, and to these three others are added. A girl, 5 years of age, came under Mr. Birkett's care in Guy's Hospital, in December, 1857. She was in a most cachectic state, and her mother said she had been ill about two months. At that time she complained of pain in the hypergastric region, which was soon followed with dysuria, and at last retention of urine. A catheter was used to relieve this difficulty. When admitted the urine dribbled away, but unless a catheter was introduced, the bladder became immediately distended. The urine was ammoniacal; contained mucus and blood, and was very offensive. The constitutional powers of the patient were much reduced, but after nutritious diet and tonics, the child's powers rallied, and she became a little stronger. In order to examine the bladder with more care the patient was placed under the influence of chloroform, and then the contracted bladder was discovered to be filled with a solid growth, a portion of which had dilated the urethra, and protruded between the vulva. A ligature was applied around the pedicle of the protruding portion, which eventually sloughed off. Some days after this the patient became very ill, and died on the 25th day after admission. Necropsy.—Suppuration in right kidney, dilated ureter and pyelitis. The walls of the urinary bladder were hypertrophied, and its cavity was dilated. Attached to the anterior wall of the viscus and the meatus, were pedunculated growths, which had dilated the meatus, and protruded through it. These consisted of delicate fibre tissue covered with epithelium. The progressive stages of the disease were next alluded to, and the cause of death in this, as well as in other

cases of a like nature, traced to irritation excited along the track of the urinary mucous membranes.

Remarks were then made upon the differential diagnosis of this disease, and those known by the name of "vascular fungus," "epithelioma," and "medullary cancer;" and it was observed that, while in polypus little or no hæmorrhage occurred, that bleeding, on the contrary, was diagnostic of the other growths. From calculus these growths might be distinguished by the absence of sound. A foreign body might be detected in the bladder by the sense of touch, but it could not be sounded. In reference to treatment the morbid specimens demonstrate that very little hope can be entertained of doing good by surgical interference, but when practicable a ligature might be safely placed around the pedicle of the growth. The paper was illustrated by drawings of the morbid specimen in its fresh state, as well as by two preparations of the disease itself.

Mr. COULSON believed that the tumours mentioned in the paper had been described by some authors as villous growths, some of which are of a non-malignant, and others of a malignant kind, the former being by far the most rare. He (Mr. Coulson) would not now allude to symptoms of tumours in the bladder; but assuming that the existence of a growth had been determined, an important practical point arises, whether the tumour is of a malignant character. Considering the frequency of malignant growths in the bladder, he thought the differential diagnosis could be made out. In malignant growths the symptoms manifest themselves more suddenly with pain and hæmorrhage; the pain is more deep-seated, as the malignant tumour usually grows from the fundus, while the non-malignant has its origin near the neck. The hæmorrhage is also more severe, continuing during the progress of the disease, and exhausting the patient. But there is another point of still more importance, to which he (Mr. Coulson) first called the attention of the Profession in 1848, the accuracy of which had been confirmed by the subsequent observations of Dr. Owen Rees and others. He alluded to the microscopical examination of the urine, and the *débris* which it contained, in which in malignant growths cancer-cells can be discovered. In these cases even the blood passed exhibited a different appearance. As regarded the treatment in malignant cases, it could only be of a palliative kind—to lessen pain and restrain the hæmorrhage; in non-malignant cases the propriety of interference must depend on the circumstances of each particular case, but the results of operations had not been hitherto of an encouraging kind.

Mr. FERGUSON said the subject was one of great difficulty, and the hints thrown out by the author might prove of great value in its elucidation. He should have been glad, however, had Mr. Birkett been more distinct in his observations regarding the cases occurring in males and females, and in young and old subjects. He had often met with large masses connected with the prostate gland (as referred to by the author) in operations for stone. Sometimes he had to return them into the bladder, but occasionally they would come out as readily as the stone itself; at other times they were found hanging by a very narrow pedicle, so that they could be removed with comparative facility. On one occasion the tumour (the enlarged middle lobe of the prostate) was quite isolated, being surrounded by the mucous membrane of the bladder. It occasioned the patient great difficulty in passing water, of which he complained more than of the symptoms of stone. After removing the calculus, he removed the projecting portion of the prostate with the lithotomy forceps. The patient afterwards died: but he could not say whether it was from the operation in question. In another case, in which the patient died, having all the symptoms of stone, a small projection was found in the neck of the bladder about the size of a walnut, which appeared to grow from the prostate gland, and to be completely surrounded by mucous membrane; it was attached by a narrow pedicle, and dropped into the neck of the bladder when the Surgeon tried to pass water. He believed if a patient could diagnose such a case, he would be justified in making an incision, as in lithotomy, and removing the offending body by pulling, twisting or ligature.

Mr. HENRY THOMPSON said, he wished to call the attention of the Society to the broad distinction existing between that rare form of tumour, for examples of which they were indebted to Mr. Birkett, and the tumours commonly called villous. The first, or fibrous polypus, were simple protrusions, at first, of the mucous membrane, and were occasion-

ally met with in various parts of the body in connexion with that membrane. Rokitsansky had particularly described their mode of formation. The latter class, however, possessed a truly villous structure, precisely resembling the villi of the chorion; and it was an interesting circumstance that there existed this homology between the diseased and healthy structure. None of these should be termed malignant, as they did not cause death by infecting the system or involving neighbouring parts, but simply by producing hæmorrhage. Each minute villus was a delicate vascular loop, which might be ruptured by a very small abrasion, or even collapse of the bladder, and bleeding was thus produced. He was satisfied that in most of those rare cases in which the pedunculated tumours referred to by Mr. Fergusson existed, their presence might be established by careful sounding during life.

Mr. BIRKETT, in replying, said, the two diseases were so essentially different that they could never be confounded. In the disease he had described there was not a trace of villous tissue; and how it could be called malignant, or how even a villous growth could be called malignant, he was at a loss to understand, unless it was from its fatal character. In the experience of twenty-five years in Guy's Hospital he had not seen a single case of anything like portions of the prostate being drawn away with the forceps in the manner described by Mr. Fergusson; hence he could not think that they were very common in relation to calculus.

## MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at the meeting of the Court of Examiners on the 4th inst. :—

ASHBY, JOSEPH FRANCIS, Clement's-inn.  
BABBAGE, WM. BERRY, New Kent-road.  
CRAWFOOT, WILLIAM MILLER, Beccles, Suffolk.  
CROMPTON, FREDERIC, Bury, Lancashire.  
FET, WALTER, Forest-hill.  
NASH, CHARLES SAMUEL, Box, Wiltshire.  
RINGROSE, ERNEST, Potter's-bar, Middlesex.  
WILKES, EDWIN, Salisbury.  
WILLIAMS, WILLIAM, Menai-bridge, Anglesea.

Also on the 10th inst. :—

BALDING, D. BARLEY, Middlesex Hospital.  
BARRETT, CALER, Gloucester.  
GASCOTEN, G. GREEN, Oxford-terrace.  
HARPER, P. HARRY, Cambridge-street, Hyde-par  
JONES, WM. PRICE, University College.  
MOON, R. HENRY, Ilfracombe, Devon.  
SMITH, THOMAS, St. Bartholomew's Hospital.  
TEEVAN, WM. FREDERIC, Regent's-park.

At the same meeting of the Council, the following gentlemen, who had been elected at previous meetings, were also admitted to the Fellowship :—

BIRD, HENRY, Newnham, Gloucester.  
COOPER, THOMAS, Slough.  
CRIDLAND, JOHN ARTHUR, Putney.  
EVERETT, DAVID, Worcester.  
HAYMAN, HENRY, Ollery, St. Mary, Devon.  
HUGHES, JOHN, Carmarthen.  
JOBSON, JOHN, Bishops Auckland.  
MARTIN, WILLIAM, Hon. E. I. Co.'s Service, Bengal.  
RANSOM, ROBERT, Cambridge.  
TAYLOR, ROBERT, George-street, Hanover-square.

Also on the 11th inst. :—

CLAYTON, RICHARD, Accrington, Lancashire.  
EVANS, BENJAMIN, Duffryn, Pembrokeshire.  
HUGHES, BENJAMIN A., St. Vincent, West Indies.  
KEMP, BENJAMIN, Leeds.  
M'CANN, JOHN, Tonge, county Waterford.  
MORGAN, WALTER, Bridgend, Glamorganshire.  
OWEN, OWEN, Leamington.  
RAY, S. KEYWORTH, Milton, near Sittingbourne, Kent.  
SELOUS, EDRIC, Gloucester-road, Regent's-park.  
WATLING, CHARLES W., Tredington, Shipston-on-Stour.

APOTHECARIES' HALL.—Names of gentlemen who passed their examination in the science and practice of medicine, and

received certificates to practise, on Thursday, June 10, 1858:—

DAVIES, WILLIAM ABEL, Aberystwith, Cardiganshire.  
NEWCOMB, FREDERICK, Grantham, Lincoln.  
PEILE, BRANSEY COOPER, Hurstpierpoint, Sussex.  
PHILLIPS, GEORGE HARRIS, Newcastle-upon-Tyne.  
PICKETT, JACOB, Ipsden, Oxon.  
SENIOR, CHARLES, Bradford, Yorkshire.

## DEATHS.

BARNSTON.—On the 28th ult., James Barnston, M.D., of Edinburgh, Professor of Botany in McGill College, Montreal, aged 28.  
BUNKER.—June 3, at Sunbury, Middlesex, Francis Bunker, aged 54.  
CURRIE.—June 8, at Charlton, Kent, Thomas Henry Currie, aged 23.  
DESRUVELLES.—M. Desruelles, Chevalier of the Legion of Honour, formerly a Professor at Val-de-Grâce, and the author of some esteemed works, has just died at Ternes, aged 68.  
SCOTT.—June 10, at Warwick Villas, Addison-road, Kensington, Robert Scott, late Madras Medical Service, aged 70.  
SNOW.—June 16, at his residence, Sackville-street, Dr. John Snow.  
STATHAM.—On the 12th inst., at Maidstone, aged 32, Sherard Freeman Statham, M.B. F.R.C.S., Surgeon Great Northern Hospital, late Assistant-Surgeon University College Hospital.

## APPOINTMENTS.

His Excellency the Governor of Jamaica has been pleased to appoint Hugh Croakery, Esq., Surgeon, Dublin, formerly Assistant-Surgeon in Her Majesty's Royal Navy, to be a Justice of the Peace for the parish of Clarendon.  
At a meeting of the Governors of the Suffolk General Hospital, held June 15th, John W. Goodwin, M.D., Cantab., was elected Physician to that Hospital.  
The Queen has been pleased to appoint C. Elliott, Esq., M.D., to be principal Medical officer for the Island of Ceylon.

MIDDLESEX HOSPITAL.—Dr. Seth Thompson having resigned the post of Physician, Dr. Goodfellow, Assistant-Physician, is a Candidate for the vacant office, and Dr. F. Weber comes forward for the post of Assistant-Physician.

APPOINTMENTS IN THE PARISIAN HOSPITALS.—The death of Baron P. Boyer has led to M. Robert being transferred from the Beaujon to the Hôtel Dieu, M. Maligne of the St. Louis goes to the Beaujon, M. Richet of the St. Antoine goes to the St. Louis, and M. Morel Lavallée of the Lourcine replaces M. Richet.

MEDICAL COLLEGIANS AT CRICKET.—The youthful members of the Royal Medical Benevolent College Cricket Club having challenged the pupils of the Rev. Mr. Tabor's establishment at Cheam, the match came off on Saturday last in the cricket-ground at the back of Mr. Tabor's residence. The match terminated in favour of the collegiates, with five wickets to go down. The return match will be played on the college cricket-ground, at Epsom, on a future day.

THE ROYAL HOSPITAL.—The third anniversary of this institution was celebrated last week at the London Tavern. The Earl of Carlisle presided. In proposing the toast of the evening, "Prosperity to the Royal Hospital," he said, he had visited the Royal Hospital at Putney, and was much struck with the comfort and cheerfulness of the patients, the completeness of the arrangements, and airiness of the building. He thought they could not do better than go and inspect the arrangements for themselves, and here he wished to tell them that that temporary building at Putney was always open for inspection. (Hear.) He was very happy to inform them that a piece of land, measuring twenty acres, at Sandon, near Croydon, had been purchased by the committee, on which it was intended to build a permanent hospital. After some further remarks, in which his lordship referred to the cheerfulness of the patients of this institution, he concluded with an earnest appeal to the charitable public to support the

Royal Hospital. Subscriptions were announced, amounting to upwards of £1400.

MUTUAL BENEFIT SOCIETIES IN FRANCE.—The *Moniteur* contains a report to the Emperor from the commission of mutual benefit societies (Sociétés de Secours Mutuels) on the situation of such institutions at the end of 1857. It appears from it that the number of the societies was 3609; that they had 470,414 members, of whom 53,533 were honorary and 416,881 participants; and that their reserved funds amounted to 18,897,920*fr.* The number of sick persons of all the societies united was, in 1857, 108,943—93,163 of them men, 15,780 women. The number of days for which they were patients was 2,126,800—1,873,435 for men, 253,315 for women, and the number of deaths was 4977. The number of sick compared to that of members was rather more than 27½ per cent. for men, and rather more than 31½ per cent. for women. The average time for which each male patient received aid was rather more than eighteen days, and each woman nearly fourteen days. Taking all the members of the societies, the average number of days on which assistance was accorded was 4.90 per cent. per man, and 4.40 per cent. per woman. From these figures it will be observed that though women are more frequently ill than men they are not ill for so long a time. After stating that mutual benefit societies, formed exclusively of workmen employed in particular manufactories, though worthy of encouragement, do not fulfil all the conditions imposed on such societies by the law of 1852, the report states that in societies regularly constituted the contribution of members is at the rate of 1*fr.* a month, and that the allowance to them in sickness is 1*fr.* a day. It says also that out of the 12*fr.* per annum paid by each member the annual disbursement is only 9*fr.* 50*c.*—namely, 4*fr.* 90*c.* for the average indemnity of 4.90 days' sickness, 1*fr.* 80*c.* for Medical attendance, 2*fr.* 5*c.* for medicines, 50*c.* for funeral expenses, 25*c.* for relief to widows and orphans. A balance therefore of 2*fr.* 50*c.* remains, out of which 1*fr.* per head is absorbed in expenses of management, so that 1*fr.* 50*c.* per member is carried to the reserved fund, to which also go the entrance fees, the contributions of honorary members, and the subventions of the Government. The report then enters into some details respecting the grant of small pensions to aged members of mutual benefit societies—a system recently adopted, but which is not yet of general application; and it calculates that in the course of a given number of years the societies will, after relieving their sick, be able to accord upwards of 200,000 pensions of from 50*fr.* to 100*fr.*

MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.—The annual meeting of the members and friends of this Society was held on Monday, June 7, at Sir Patrick Dun's Hospital, Sir Henry Marsh, Bart., President of the College of Physicians, in the chair. Sir Henry Marsh, in his opening address, alluded to the presence in the meeting of the founder of the Society, Dr. Kingsley, of Roscrea. We regret to state that it appeared, in the terms of the second resolution, "That the amount of finances for distribution among the claimants for relief was wholly disproportionate to their necessities." The meeting, however, pledged itself in the same resolution, "to spare no exertion to render the Medical Benevolent Fund Society worthy of its objects, and of the Irish Medical Profession." Dr. Montgomery, in moving, "That the munificent donations of £50, in addition to his former donations of £361, by Dr. Kingsley; and of £50 by Dr. Purdon, in addition to his former donations of £110; and of £100 by Dr. Wilkinson to the funds of this society during the past year, call for the liveliest thanks of this meeting, and that these gentlemen do kindly accept the hearty acknowledgments hereby presented to them for their liberality in the cause of this most useful charity," remarked, in reference to Dr. Kingsley, "that it had been said by a very high authority indeed, that 'the man who rules his own spirit is a greater man than the man who takes a city.' That, certainly, was a triumph in individual economy, no doubt, and one of a very high order; but it was no mean triumph to be able to move the spirit of society around you, and that had been done in a very remarkable way by the gentleman to whom he alluded. That gentleman, originally, at the prompting of his own good heart and his own benevolent spirit, originated the notion of the very existence of the society. He fostered it by his personal exertions, and succeeded in establishing it by his energy and moral influence, and by another course that had a very

powerful effect with almost all men—he lent it the resources of his own purse; and he did this in a way, in the first instance, that placed him among those who were said 'to do good by stealth, and blush to find it fame;' and almost the largest donation that had been made to that society had been made by that gentleman anonymously, to the amount of £361. It had been said that one of the greatest triumphs that a great statesman could lay claim to was to be able to read his history in the nation's eyes. The gentleman to whom he alluded might not, perhaps, be able to 'read his history in the nation's eyes;' but he would read it in the consolation of the widow, and in the consolation of the poor, broken-down member of the profession to which he belonged."

## VITAL STATISTICS OF LONDON.

Week ending Saturday, June 12, 1858.

## BOOKS RECEIVED.

The North American Medico-Chirurgical Review. May. 1858.  
Humboldt's Cosmos. Vol. IV., part I. London: 1858.  
The Principles and Practice of Veterinary Medicine and Surgery. By William Haycock, M.R.C.V.S. London: 1858.  
Notes on the Surgery of the Crimean War; with Remarks on Gun-shot Wounds. By George II. B. Macleod, M.D., F.R.C.S. London: 1858.  
Epilepsy, and other Convulsive Affections; their Pathology and Treatment. By Charles Bland Radcliffe, M.D. London: 1858.  
Four Letters to Sir James Clark, Bart., on Administrative Reform in relation to the Medical Schools and the Examining Boards. By Alexander Harvey, M.D. London: 1858.  
On Elephantiasis in Travancore. By E. J. Waring, Esq. Calcutta: 1858.  
On the Reciprocal Action of Metals and the Constituents of Well and River Waters. By Henry Medlock, Esq. London: 1858.  
On the Causes of Idiocy; being the Supplement to a Report by Dr. S. G. Howe and the other Commissioners at Massachusetts. Edinburgh: 1858.  
Remarks on the Condition, Necessities, and Claims of the Universities of Scotland. By a Graduate. London: 1858.  
The Diagnosis of Surgical Cancer. By J. Z. Laurence, F.R.C.S., M.B. Second Edition. London: 1858.  
Sanitary Science. By W. T. Robertson, M.D. London: 1858.  
Archives of Medicine. Part II. By Lionel S. Beale, M.B. London: 1858.  
The Use of the Microscope in Clinical Medicine. Part III. By Lionel S. Beale, M.D. London: 1858.

## TO CORRESPONDENTS.

*Inquirer.*—We have often expressed our opinion that such testimonials from Medical men are highly objectionable.

*Mr. Wilson.*—It is not necessary to refer to Dr. Webster. See Simpson's Homoeopathy.

Perhaps the Correspondent who sent us the circulars of the Surgeon, Chemist, and Dentist of Poplar New Town will say if the person is a member of the College. We do not find his name in the Directory.

*Chemist.*—We believe there is no doubt whatever of the election of Dr. Lyon Playfair to the Chemical Professorship in the University of Edinburgh. The only question is whether the election will be unanimous.

*Dr. Jones.*—The words of the statute (1 Vict., c. 85, sec. II.) are these:—"Whoever shall administer, or cause to be taken, any poison, or other destructive thing, with intent to commit murder, shall be guilty of felony, and being convicted thereof, shall suffer death."

*Mr. Richardson, Fitchin,* will find some account of the treatment of nœvi by the injection of perchloride of iron in the report of a recent discussion on a paper of Mr. Walton's at the Medical and Chirurgical Society, and in Mr. Spencer Wells's Lecture on "Cancer Cures and Cancer Cures," published in our number for July 18, 1857.

*Query.*—The epitaph is as follows,—

"Here lies Dame Mary Page,  
Relict of Sir Gregory Page, Bart.  
She departed this life March 4th, 1738,  
in the 66th year of her age.  
In 67 months she was tapped 67 times,  
And had taken away 240 gallons of water."

THE ROYAL MEDICAL BENEVOLENT COLLEGE AND THOSE WHO SHOULD SUPPORT IT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Whilst reading in your journal of June 5 the statement of the "dissentient Governors," I also received the 8th annual report of the Council of the Royal Medical Benevolent College, and then I did truly exclaim, "Ego sum inter suspiria et lacrymas." I sigh at the "statement," lest by this schism between two classes of Governors, "such a noble edifice may be brought about their ears." I lament at "the report" to observe that out of 25 or 30,000 Medical men (computed in England and Wales), only £3262 18s. 6d. should be the last annual amount of subscriptions—the more so, as a large proportion of this sum is given by lay or non-medical subscribers, as proved by my small list as Honorary Secretary, which shows one in three of the latter class.

To what can we ascribe such apathy and indifference in our brethren? I would fain be charitable—yet, as "least said is soonest mended," I would simply entreat, nay, implore every Medical man, if with only a practice of £200 a-year, to consider well the matter, and contribute his annual mite to the support of such a noble institution—and not withhold it because he has now a good practice, is in good feather, and has neither chick nor child, etc. etc. (usual reasons). But let him remember that these are the very reasons why he should contribute to the support of his less fortunate brethren. If every man would do this, this schism between the Governors would soon subside, and then indeed, our sons might and would, as matter of course, be educated for £25 or £30 a-year, vice £40.

If any further argument be wanted, I would only refer them to the voting paper of the late May election, where, out of ten candidates for pensionerships, only three are to be returned, and out of thirty-five for foundation scholarships, only five are chosen!! Then leaving upwards of 160 fatherless children to be brought up by their widowed mothers!!! and some of these in destitution!!!!

East Rudham, June 11, 1858. I am, &c. FRED. MANBY.

COMMUNICATIONS have been received from—

Dr. ACLAND, Oxford; Professor SIMPSON, Edinburgh; Dr. CHAMBERS; Dr. HERBERT BARKER, Bedford; Dr. ROLLESTON, Oxford; Dr. REMAK, Berlin; Dr. R. D. THOMSON; Mr. WEEDEN COOKE; Mr. JABEZ HOGG; Mr. GRANTHAM; Dr. PEACOCK; Mr. GRIFFIN, Weymouth; Dr. W. T. ROBERTSON; Mr. HAVILAND; M. A. B.; REGISTRAR GENERAL; Mr. WILSON; SECRETARY GENERAL BOARD OF HEALTH; Mr. LEACH; Dr. DAVIS; Mr. GIBSON; Mr. COLLET; REGISTRAR GENERAL, Edinburgh; Mr. RIVERS; Dr. GOODWIN; Mr. GROVE; Mr. THOMPSON; Mr. DOLBY; Mr. JONES; Dr. SYLVESTER; Mr. MUGGERIDGE; Mr. J. ADAM; Mr. J. BLOWERS; Mr. J. YATE; Dr. GAIRDNER, Edinburgh; Mr. H. SMITH.

## APPOINTMENTS FOR THE WEEK.

June 19. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m.; Charing-Cross, 1 p.m.

21. Monday.

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.; Orthopaedic Hospital, 2 p.m.

22. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.  
ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m.: Papers by Dr. GARROD, Dr. WILSON FOX, Mr. TOYNBEE, Dr. JOSEPH RIDGE, Dr. J. W. OGLE, Mr. CHARLES HAWKINS, Dr. P. FRASER, and Mr. T. HOLMES.  
ZOOLOGICAL SOCIETY, 9 p.m.

23. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Orthopaedic Hospital, 2 p.m.  
GEOLOGICAL SOCIETY, 8 p.m.

24. Thursday.

Operations at St. George's, 1 p.m.; Middlesex, 1½ p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.

25. Friday.

Operations at the Moorfields Ophthalmic, 10 a.m.; Westminster Ophthalmic, 1½ p.m.; Great Northern, 2 p.m.

## EXPECTED OPERATIONS.

King's College Hospital.—The following operations will take place this day (Saturday), at 2 o'clock:—

Lithotomy; excision of mamma; hare-lip. By Mr. FERGUSON. Removal of bone from tarsus. By Mr. WOOD.

## Wines from the Cape of Good Hope.

W. and A. GILBEY, 357, Oxford-street, importers of the finest Wines, which Her Majesty's Government admits at half duty. Port, Sherry, Madeira, Marsala, &c., all 20s. per dozen. Two Samples for 12 stamps. Excellent Brandy, 80s. per dozen. For the purity of our Cape wines, see Dr. Letheby's analysis. Cross checks, "Bank of England."

## The Medicated Cod Liver Oils,

comprising  
OLEUM MORRHUE CUM QUINA.  
OLEUM MORRHUE CUM FERRI IODIDO.  
&c. &c. &c.

Prepared only by SAVORY and MOORE, 145, New Bond-street.

## Liquor Pepsinæ.—A Convenient and

EFFECTUOUS PREPARATION BY  
SAVORY and MOORE, 145, New Bond-street.

## Horniman's Pure Tea, the leaf

not coloured.—Rich full-flavoured TEA of great strength is thus obtained, as importing it not covered with powdered colour prevents the Chinese passing off the low-priced brown autumn leaves as the best. The "Lancet" (Longmans, p. 318) states of Horniman's teas:—"The Green not being covered with Prussian blue, etc., is a dull olive; the Black is not intensely dark." Wholesome and good Tea is thus secured. Prices 3s. 8d., 4s., and 4s. 4d. per lb. London agents:—Pursell, 78, Cornhill; Elphinstone, 227, Regent-street, 366, Oxford-street, and 21, Throgmorton-street, Bank; Wolf, 75, St. Paul's-churchyard; Dodson, 95, Blackman-street, Borough. Sold in Packets by Horniman's Agents in all parts of the Kingdom.

WINES FROM SOUTH AFRICA.

## Denman, Introducer of the South

AFRICAN PORT, SHERRY, &c., 20s. PER DOZEN, BOTTLES INCLUDED.

The well-established and daily-increasing reputation of these Wines in a public estimation renders any comment respecting them unnecessary.

A PINK SAMPLE OF EACH FOR 24 STAMPS.

Wine in cask forwarded free to any Railway-station in England.  
EXQUISITE BRANDY, PALE OR BROWN, 15s. PER GALLON, OR 80s. PER DOZEN.

Terms Cash. Country orders must contain a remittance. Cross cheques, Bank of London. Price Lists forwarded on application.  
JAMES L. DENMAN, 65, FENCHURCH-STREET.

### BROUGHAMS.

Kinder, M'Naught, and Smith,  
MANUFACTURERS, WORCESTER, beg respectfully to invite the attention of professional men to their improved Medical Broughams, as under:—

Width of Seat.	Weight.	Price.
3 ft. 5 in. . . . .	7½ cwt. . . . .	85 Guineas.
3 ft. 6 in. . . . .	8½ cwt. . . . .	95 Guineas.
3 ft. 7 in. . . . .	9 cwt. . . . .	100 Guineas.

The latter, including a segmental front, with seat for third person.

These Carriages are constructed, by the aid of machinery, of the best material, are of excellent workmanship, and particularly adapted to the wants of medical men, either in town or country. Drawings and other particulars forwarded on application.

## ELECTRICITY.

PULVERMACHER'S MEDICAL ELECTRO-GALVANIC CHAINS—for Rheumatism, Indigestion, and Nervous and Paralytic Complaints, &c. &c. The profession have in these Chains the best, simplest, and most effective means of applying Galvanism. No pain is felt, and the patient can, without attendance, use them himself with efficiency. The popularity they have obtained in almost all parts of the world, and the numerous cures they have effected, together with the eulogiums passed upon them by the most eminent of the faculty, suffice for any further details. See the works of De la Rive, Becquerel, Duchenne, Pouillet, Ganot, Du Moncel, and the medical and scientific periodicals. Adopted by the Académie de Médecine, Paris, and by all similar institutions in Europe; also rewarded at the Universal Exhibition. £10,000 damages. Both the High Courts of England and France condemned Mr. C. Meinig (ex-agent) in this sum for infringing the inventor's rights. Let counterfeiters therefore, be cautious.—Chains to be worn on the body, 5s. and 10s. 6d.; the 15s., 18s., and 22s., are the most useful. Free per post. Batteries, £1 10s. to £3.—J. L. PULVERMACHER & CO., 73, Oxford-street, (adjoining the Princess's Theatre), London.

## The Sydenham Trousers, 17s. 6d.;

COATS, 35s.; and WAISTCOATS, 8s. 6d.—It is well known how great an influence is exercised upon the health by the mode of dress. Many disorders, and still more of the common indispositions or irregularities, can be distinctly traced to imperfect adaptation of the clothes to the functions of the body and the limbs. This is true of adults as well as of children, though, perhaps, not to the same extent. The Sydenham construction of the whole attire is directed to secure a perfect fit in all positions without restraint, strain, or incumbrance, so that the limbs retain as free play as if in PURIS NATURALIBUS. The Boy's Complete Suit (24s.) is also eminently adapted for these purposes. The material and workmanship are the best which can be commanded. The assortment open for selection is immense, and includes all that is most fitted for the season. The assortment of Sydenham Alpaca Overcoats (12s. 6d.) for Summer wear deserves attention, as these goods have been made with unusual care.

SAUEL BROTHERS, Merchant Tailors, 29, Ludgate-hill.

## Bass's East India Pale Ale, Barclay's

Porter and Stout, in 18-gallon Casks, Bottles, Half-Bottles, and Imperial Pints.

BERRY, Bros. and Co., 3, St. James's-street, London, S.W.

## Carriages, New and Second-hand, of

superior style, sterling quality, and finest finish at reasonable rates, for cash, credit, job, or exchange. Circular of prices on application. Credit given when required. Buyers should take carriages on trial, with power to purchase by yearly payments, and thus prove them.

OFFORD'S PATENT MEDICAL MAN'S BROUGHAM MANUFACTORY, 79, WELLS-STREET, OXFORD-STREET.

## For Infants.—The British Feeding

BOTTLE (registered) may be placed in any position without the Food running out. The supply can be regulated by a stop-cock; being electroplated, it may be instantaneously cleaned. Unlike wood, ivory, or bone, it is impervious to moisture, cannot crack or become sour; there is no possibility of the infant drawing air with the food.

By W. T. COOPER, Pharmaceutical Chemist, 28, Oxford-street, London.  
Price 7s. 6d., or free to any Railway Station, 8s. 6d.

## Whicker and Blaise (late Savigny

and Co.), 67, St. James's-street, beg to call the attention of the

Medical Profession to their Registered MERCURIAL VAPOUR-BATH, for the treatment of Syphilitic Affections, &c., (see "The Lancet," March 14th, 1857), as used at St. George's, the Westminster, King's College, the Lock, the Hospital for Children, and by many Professional gentlemen.

It is also well adapted for Fumigation with Sulphur, Iodine, &c., in the Treatment of Catarrhus Diseases.

To be had only at 67, St. James's-street.

## Struve's Sektzer, Fachingen, Marien-

BAD, VICHY, and other MINERAL WATERS. Royal German Spa, Brighton. Under Her Majesty's especial patronage. Struve's Pump Room and Promenades, for the perfect dispensing of the most renowned Continental Mineral Waters, is NOW OPEN for the Thirty-fourth Season. The bottled Mineral Waters are sold throughout the year at the Pump Room, and by George Waugh and Co., Pharmaceutical Chemists to the Queen, 177, Regent-street (west side), London; and other respectable Chemists in London and the provincial towns, where a Prospectus, with the highest Medical testimonials, may be obtained, gratis.

CAUTION.—To distinguish these from all other Waters, each bottle is secured by a label and red-ink stamp, bearing Struve and Co.'s name.

## Moveable Artificial Eyes.—The Prize

MEDAL of the Great Exhibition, 1851, was awarded exclusively to the EYES made by W. R. GROSSMITH, 175, Fleet-street, London, Maker to the Senior Surgeons of the Ophthalmic, Bartholomew's, St. Thomas's, St. George's, and all the principal London Hospitals. They are fitted in a few hours, without pain or operation, in every case, where sight has been lost; they effect a perfect MOVEMENT, in accordance with the action of the natural eye; the colours of the Iris are closely matched, and they are the only Artificial Eyes yet invented, not liable to Croak in wearing. Sent by post to all parts of the world, from GROSSMITH'S Artificial Eye, Leg, Hand, and Nose Manufactory, 175, Fleet-street, London. Established 1760.

## Great Saving in the Purchase of Six

GROSS of NEW MEDICAL GLASS BOTTLES and PHIALS, assorted to suit the convenience of Purchasers, at ISAACS and SON, Medical Glass Bottle Manufacturers.—London Warehouses, 24 and 25, Francis-street, Tottenham court-road, London, W.

	s.	d.
6 and 8 oz., any shape, plain, or graduated	8	0 per gross.
3 and 4 oz. ditto ditto	7	6 do.
1 oz. Moulded Phials	4	6 do.
1 oz. ditto	5	6 do.
1½ oz. ditto	6	0 do.
2 oz. ditto	7	0 do.

NOTICE.—S. ISAACS and SON beg to inform the Medical Profession, that they have REMOVED to larger premises as above, and hope to be favoured with their commands. A remittance not required till the goods are received. Packages free. Delivered free within seven miles. Post-office Orders payable to "S. Isaacs and Son," at Tottenham-court-road. Bankers: Unity Bank.

## Crosse and Blackwell, Purveyors in

Ordinary to Her Majesty, respectfully invite attention to their PICKLES, Sauces, Tart Fruits, and other table delicacies, the whole of which are prepared with the most scrupulous attention to wholesomeness and purity. The practice of colouring pickles and tart-fruits by artificial means has been discontinued, and the whole of their manufactures are so prepared that they are not allowed to come in contact with any deleterious ingredient. A few of the articles most highly recommended are, Pickles and Tart Fruits of every description, Royal Table Sauce, Essence of Shrimps, Boho Sauce, Essence of Anchovies, Jams, Jellies, Orange Marmalade, Anchovy and Bloaters Pastes, Strasbourg and other Potted Meats, and Calf's-Foot Jellies of various kinds for table use. C. and B. are also sole agents for M. Soyer's Sauces, Relish, and Aromatic Mustard; and for Carstairs' Sir Robert Peel's Sauce, and Payne's Royal Osborne Sauce. The above may be obtained of most respectable Sauce Vendors throughout the United Kingdom; and Wholesale of

CROSSE and BLACKWELL, 21, Soho-square.

## ORIGINAL LECTURES.

## LECTURES

ON

THE ANATOMY, INJURIES, AND DISEASES  
OF THE HEAD,

DELIVERED IN THE

*Chaire of the Royal College of Surgeons of England.*

By PRESCOTT HEWETT,

Professor of Anatomy and Surgery to the College.

## ON FRACTURES OF THE SKULL.

## LECTURE IV.

(Continued from p. 597.)

IN looking attentively into the various opinions which have from time to time been brought forward to explain whence this fluid is derived, you will soon perceive that all these opinions may be reduced to two classes. One, in which the fluid is said to be nothing but the serum of the blood; the other, in which it is said to be the secretion from some membrane.

At first it was thought that this fluid was nothing more than the serum from a clot of extravasated blood, lying over, and in direct contact with, the fracture. Such was the opinion broached by M. Laugier in the year 1840, who, it so happened, found in the dissection which he made a clot of blood in such a position, that its serum might have percolated through the fracture. But it was soon perceived that this explanation was of no real value; and such has been the weight of the arguments urged against M. Laugier's first opinion, that he has been forced to call in to his aid the exudation of the serum from the lacerated vessels lying along the broken bone and the neighbouring soft parts.

M. Chassaingnac, in a most elaborate paper, has also endeavoured to trace this fluid to the serum of the blood, but in a different way. Looking to the large number and to the size of the venous sinuses which are crowded round the petrous bone within the skull; looking, moreover, to the intimate and peculiar connexion of these sinuses with this bone, to which they are all firmly attached by their outer wall, tightly stretched, and very thin, M. Chassaingnac thinks it all but impossible that a fracture of this petrous bone should occur, without a laceration or a fraying of this thin outer wall of some one of these sinuses.

In a man who had fallen from a third story, and from whose ear there had been a sero-sanguineous discharge, M. Chassaingnac, on examining the body, found in the outer wall of the sinus a minute opening, not larger than a pin's head, communicating with a fracture leading into the internal auditory canal. An opening so minute as this might, he thought, give passage to the colourless part only of the blood, but a larger opening would lead to the escape of the blood itself.

Such, then, are the opinions as to the serum of the blood being the source of this watery discharge. Does either of these opinions satisfactorily account for the appearances at present under consideration? Certainly not. The quantity of fluid often poured out in such cases cannot be accounted for by either of M. Laugier's suppositions; and M. Chassaingnac's explanation does not fare better, when tested by dissections. In a case in which a copious and colourless discharge took place for several days from the ear, in connexion with fracture of the petrous bone, I found the lateral sinus, from its mastoid portion to the jugular vein, blocked up by a firm coagulum, of a rusty brown colour, and adherent to the inner coat. This coagulum, which was evidently of several days' standing, totally precluded the idea of the limpid fluid being the colourless part of the blood circulating through the sinus, which, in fact, was no longer pervious. There could have been no circulation through the sinus for several days, and yet, notwithstanding, the watery discharge went on as long as the patient lived. And then let us add that the chemical analysis of the fluid proves, beyond all doubt, that it is not the serum of the blood.

But, if the petrous bone is thus evidently connected with large venous sinuses, so too is it connected, and that even

VOL. XXXVII. No. 978. NEW SERIES, No. 417.

more intimately, with several secreting membranes. And to each of these membranes you will find that the watery discharge from the ear has been ascribed.

This watery discharge was said to belong to the membrane lining the different cavities of the internal ear. The injury sustained by this membrane in the fractures which so frequently involve the internal ear; the state of the fenestra ovalis, with its membrane torn, and the free communication thus established between the internal and the middle ear, naturally suggested the idea of the escape of the liquor cotunnii into the cavity of the tympanum, and thence outwards.

Then, the cavity of the arachnoid was assigned as the source from which is derived this watery discharge. The cavity of this membrane may, now and then, be laid open by the laceration of the dura-mater covering over the fracture; but, as the arachnoid cannot possibly let escape a fluid which it does not contain, it has been suggested that the injury gives rise to an increase in the natural secretion, and hence the watery discharge.

In presenting to the Société de Chirurgie de Paris, a broken petrous bone, connected with which there had been a copious watery discharge from the ear, M. Robert stated that he believed that the watery fluid had proceeded from the membrane lining the internal ear. This opinion was stoutly opposed by Auguste Bérard and M. Nélaton, who maintained that the fluid in such cases could not be due to the internal ear, but, in all probability, to the escape of the cerebro-spinal fluid. And recent investigations have proved the correctness of this view, in some cases, at any rate.

But, in order that we may clearly understand how it is that the cerebro-spinal fluid can thus get out of the ear, let me, for one moment, revert to a few anatomical details.

It is with the meatus internus only, and the parts therein contained, that we shall have to deal.

Differing from most of the cerebral nerves, the seventh pair, you will remember, run some distance in a bony canal, before they reach the foramina through which they are to pass to their destination. Into this canal, the meatus internus, a tubular sheath of the cerebral membranes accompanies these nerves—the pia-mater blended with the neurilemma—the arachnoid forming a large, loose, funnel-like process, extending some distance down the canal, when it reflects itself on to the dura-mater, so as to become continuous with the parietal arachnoid. The cerebro-spinal fluid which is to be found everywhere, between the arachnoid and the pia-mater, distends this loose, funnel-like process of the arachnoid in its whole length; and, as the nerves are much smaller than their bony canal, the meatus is always filled with fluid. And, by means of this funnel-like process, you will also remember that the sub-arachnoid space in the meatus is, moreover, continuous with the large sub-arachnoid space at the middle and inferior part of the brain, in which is always accumulated a large quantity of fluid. And, lastly, let me add that the dura-mater, prolonged into the meatus internus, and lining it throughout, is very much attenuated, especially at the bottom of the canal, where it becomes still thinner.

This, then, is the anatomical disposition of the parts contained in the meatus. And this it was which led Auguste Bérard to think that the watery discharge from the ear might be the cerebro-spinal fluid, escaping through a fracture involving the meatus internus, and accompanied by a laceration of its membranes.

It is to the discussion which then ensued in the Société de Chirurgie, after the presentation of his specimen, that is due the memoir of M. Robert, certainly one of the most valuable of all the papers which have been published on the watery discharges following injuries of the head.

Having ascertained by a careful dissection that the membranes in the meatus internus were actually torn in the very specimen which he had presented to the Société de Chirurgie, M. Robert followed up the subject by getting the watery discharge examined chemically.

Analysed by M. Chatin, the chemical composition of this watery discharge was found to be the same as that of the cerebro-spinal fluid, the great characteristic in both being the very small proportion of albumen, and the large quantity of chloride of sodium. Satisfied as to these points, M. Robert then resorted to an experiment on the dead subject. The skull-cap was removed, and the cavity of the tympanum freely laid open, especial care having been taken so as to avoid

lacerating the dura-mater. The ossicula were taken out, and a small chisel applied across the inner wall of the tympanic cavity, just over the fenestra ovalis. A sharp blow on the chisel at once cracked the petrous bone across, and in a few seconds, oozing through the crack, was seen a limpid fluid, the discharge of which became copious and continuous, as soon as the body was laid over the table, with the head hanging down. It was subsequently ascertained that the fracture, thus artificially produced, involved the meatus internus, and that the membranes lodged in this canal were also torn.

Such were the results of M. Robert's investigations. Anatomy, chemistry, dissection of morbid specimens, experiments on the dead subject, all led to the conclusion, that the watery discharge from the ear, after a severe injury of the head, is due to the escape of the cerebro-spinal fluid.

And such, too, is the result of the researches of Mr. Hilton, who, for many years, has closely observed everything appertaining to this subject. "I do not think," says Mr. Hilton, "there can now be any doubt or question about the clear fluid which escapes from the ear in cases of fractured base, consisting of cerebro-spinal fluid. Some years ago, a boy, who had sustained a severe injury of the head, was admitted into one of the wards of Guy's Hospital. He presented the ordinary symptoms of fractured base, and a small quantity of a thin, clear fluid was observed oozing out of one ear. It occurred to me, that if this really consisted of cerebro-spinal fluid, it ought to escape in much larger quantity, on artificially inducing venous congestion of the cerebral circulation. I therefore pressed upon the jugulars, and with the other hand forcibly closed the patient's mouth and nose, so as to suspend the respiratory process for a short time, until, in fact, his face became red and turgid from venous congestion. As I had anticipated, in a very few moments, the fluid began to flow much more rapidly from the external ear, so much so indeed, that I was quickly enabled in this way to collect even half an ounce of it."

This escape of the cerebro-spinal fluid through the ear implies, then, as a matter of course, a fracture of the meatus internus communicating with the tympanum, and a laceration of the cerebral membranes within the meatus, as well as a laceration of the membrana tympani. Nay, more, the escape of this fluid is held to prove that the fracture follows a particular course—that it, in fact, cuts across the petrous bone. This is the rule laid down by M. Robert: "*La fracture coupe en travers la portion pierreuse du temporal*;" and Mr. Hilton is no less explicit: "The fracture bisects the internal auditory canal."

I have now laid before you the various opinions which from time to time have been put forward as to the source and nature of this watery discharge from the ear, after a severe injury of the head. But how comes it that so many different sources have been assigned to this fluid? This leads us directly to the question whether this fluid does indeed always proceed from one and the same source. Now this question must at once be answered in the negative. The great error pervading the investigations on this subject is, that each inquirer, in bringing forward his own opinion, has attempted to exclude all other opinions, as if this watery discharge might not in different cases proceed from different sources. I have not the slightest doubt that in some cases this watery discharge is due to the escape of the cerebro-spinal fluid; neither have I any doubt that in many cases it has nothing to do with the cerebro-spinal fluid, and that it must therefore have some other source.

I proceed, now, to test the real value of these opinions by cases which have fallen under my own notice; and, for this purpose, I shall select two cases, in which the difference as to the fluid was strongly marked.

A man, aged 52, was admitted into St. George's Hospital, under the care of Mr. Cæsar Hawkins, in March, 1852, with a profuse discharge of a clear, watery fluid from the left ear. The patient having, it appeared, fallen, four days before his admission, in some kind of a fit, had struck the back part of his head against a stone pavement. He had been insensible for an hour after the accident, and, after recovering, had immediately noticed the discharge from the ear, which had continued ever since, and had not been preceded by any bleeding. There was a small scalp-wound, not exposing the bone, on the right side of the occipital, near the lambdoid suture; but no fracture could be detected in this, or any other part of the skull. The watery fluid, of a very faint

pinkish hue, dropped freely from the ear, the flow being increased when the patient was speaking; there was great pain in the head, and the patient's manner was slow and oppressed; the countenance was heavy, and of a dusky hue; the hearing on the left side was much impaired, in fact, all but lost; but there was no paralysis of the facial nerve. The patient was perfectly sensible, with a pulse laboured, and at 56. Symptoms of diffuse inflammation of the membranes soon made their appearance, and the man lived only four days after his admission into the Hospital, the discharge of watery fluid having continued, with but little variation, up to the time of his death. A line of fracture was traced from the neighbourhood of the right lambdoid suture, obliquely through the occipital, to the left side of the foramen magnum; proceeding from thence through the lateral sinus, close to the foramen lacerum posterius, it reached the petrous portion of the temporal, which it cut across between the meatus internus and the superior semicircular canal, and having passed about midway across the petrous bone, the fracture made a sudden bend, and then proceeded along the anterior surface of this bone, towards the inner opening of the carotid canal, where it terminated. In this course the fracture at its bend caught the bottom of the meatus internus, and, passing through the vestibule, reached the tympanum, the cavity of which was widely laid open. In addition to this fracture, a slight fissure, so slight that at first it was hardly perceptible, was found passing perpendicularly through the crebriiform plate at the bottom of the meatus, and this fissure was traced backwards through the floor of the meatus into the jugular foramen. No laceration was detected in any part of the dura-mater, save at the bottom of the meatus internus, where its attenuated lining presented a slight laceration, exactly corresponding to the perpendicular fissure which I have just mentioned. There was no laceration of the lateral sinus; but the cavity of this channel, from its mastoid portion to the jugular vein, was blocked up by a firm coagulum of a rusty brown colour, and adherent to the inner coat. The membrana tympani was ruptured in two different places; one of these ruptures was close to its outer margin, and the other and larger of the two was in the centre.

In this case, previous to the dissection of the fracture, a slender pig's bristle, having been gently passed to the bottom of the meatus, and immediately above the nerves, made its way into the tympanic cavity, from whence, with a little management, it was brought through the central rupture in the membrana tympani, thus plainly showing the course the cerebro-spinal fluid had taken.

The second case is that of a lad, aged 11, who was admitted into St. George's Hospital, under the care of Mr. Tatum, in December, 1852, insensible, and in a state of extreme collapse, with profuse bleeding from the left ear, the history being that he had, a short time previously, fallen from a first-floor window. There was no external bruise, but a large collection of blood was found spreading over the back part of the left side of the head. The bleeding from the ear continued to be profuse for nine or ten hours; it then began to diminish, the blood became thinner, and ceased flowing in from twelve to thirteen hours. On the following day, the meatus was clogged with half-dried, clotted blood; the boy had so far recovered as to be able to answer the questions put to him. He went on improving for three days, during which time the dried blood disappeared from the meatus, which then became somewhat moist, and partially filled with epithelial scales and fat globules; the moisture extended beyond the meatus on to the concha, but, as yet, there was no actual serous discharge. On the fourth day, a thickish sero-purulent-looking fluid, of a pinkish colour, oozed from the ear. On the fifth day, the discharge, still of a slight rose colour, had become all but limpid, and much increased in quantity, so much so that, when the patient was lying on the right side, the concha of the left ear was filled with fluid; the pillow-case was extensively stained with the fluid which had run from the ear. On the sixth day, the watery discharge still continued; it was perfectly clear, but suspended in it was a thick, puriform-looking secretion, which, examined microscopically, proved to be lymph and pus cells. And thus matters went on for two or three days; the watery discharge gradually diminished, so that the meatus again presented merely a slight moisture. And, from this time, all that was observed about the meatus was a slight puriform discharge, which ceased for a time, then re-appeared, and finally ceased altogether. Some days after

the accident, this patient was also observed to be deaf on the left side, but there was no affection of the facial nerve. The boy appeared to be going on well for some thirteen days; symptoms of cerebral mischief then began to show themselves, and he sank on the sixteenth day after the accident:—A little above the left semicircular ridge, the occipital bone presented a transverse fracture, which was somewhat comminuted; one part of this fracture ran into the left branch of the occipito-parietal suture, the bones of which were separated, and arrived at the mastoid portion of the temporal, it stretched under the lateral sinus, and then into the petrous bone, which it cut across, passing immediately through the superior semicircular canal, and, when in the neighbourhood of the hiatus Fallopii, it made a bend, and then proceeded obliquely forward into the foramen lacerum medium, where it ended. The cavity of the tympanum was crossed by the line of fracture, and so too was the internal ear, but the meatus internus remained unbroken and untouched. The membrana tympani was torn from its connexion with the ring at its upper margin. The cavity of the tympanum, as well as the whole line of fracture, and the internal ear, were all filled with lymph partially organized, and of a red colour, and in several places pus was detected between the bones. At the base of the brain there was extensive bruising of the brain-substance in several different places, and here too the sub-arachnoid tissues were extensively inflamed.

## ORIGINAL COMMUNICATIONS.

### ON THE RESTORATION OF MOTION

BY THE

### RUPTURE OF THE UNITING MEDIUM OF PARTIALLY ANCHYLOSED SURFACES.

By BERNARD BRODHURST, Esq.

Assistant-Surgeon to the Royal Orthopaedic Hospital.

(Continued from page 599.)

#### PARTIAL ANCHYLOSIS OF THE HIP-JOINT.

*Case 6.*—C. M., an officer in the Royal Engineers, was returning from the trenches before Sebastopol, November 24, 1854, with a friend, when he was struck in the median line of the abdomen, immediately below the umbilicus, by a bullet. In this position the ball struck on a button, and, glancing, entered about three inches above the pubis, and passed into the groin, carrying with it portions of a match-box, and other things, which it had encountered in the pocket of the friend, through which it passed before it reached its destination. The ball passed deeply into the upper part of the thigh, just below Poupert's ligament, displacing the femoral vessels outwards. Inflammation resulted, and an abscess formed, but the ball remained. Inflammation extended to the hip-joint, and confined the patient to bed, with scarcely any power of movement, until the following April. Then it was discovered that the limb was fixed at an obtuse angle, and that the motion of the joint was lost.

It would be tedious to follow my patient in his wanderings during the years 1855 and 1856. Suffice it to say, that he sought the advice of the most experienced Surgeons in London and in Paris, and tried baths innumerable, in the south of France and elsewhere. The result of all this was, that his health was restored; but the limb remained immovable as before.

When he placed himself under my care, in March, 1857, I found the thigh flexed at an obtuse angle, and immovable, so that when he stood upright the sole of the foot was two inches from the ground.

March 30.—The full effect of chloroform having been obtained, the pelvis was firmly fixed; and, with the assistance of Dr. Gibb, I endeavoured to flex the thigh. After a considerable effort, a band of adhesions yielded; but the joint was not free. A renewed effort was made, and the remaining portion was ruptured with a loud snap. This last-mentioned portion was a narrow band of bone external to the capsule. The limb was immediately afterwards encased in a splint. Considerable pain was felt both in the hip and in the knee on recovering from the effects of the chloroform. This, however,

soon subsided, and he slept well at night without an opiate. After this time pain was only felt on moving the limb. He left his bed on the seventh day, and motion of the limb was commenced one week later. Passive motion of the limb occasioned great pain in the neighbourhood of the hip-joint, and it was borne with heroic fortitude. This pain was attributable rather to the presence of the ball, which was most painfully felt whenever motion of the joint was attempted, than to the condition of the joint itself. Indeed, so much pain was caused by the presence of the ball, that it became a serious question whether an attempt should not be made to remove it. Happily, however, it soon moved from the position which it had so long occupied; less irritation was then created, and gradually it ceased to be felt.

At the end of the third week he could bear almost the entire weight of the body on that leg. Motion was slow in being acquired, and a powerful effort was necessary to overcome the largely developed muscles of the thigh, which became rigid on making the least attempt to move the limb. However, by great perseverance in the use of passive motion, the thigh could be flexed beyond a right angle, and it could be perfectly extended.

#### PARTIAL ANCHYLOSIS OF THE KNEE-JOINT.

*Case 7.*—A. M., 15 years of age, a healthy-looking boy, from the north of England, was placed under my care in the spring of the year 1854. In 1844 he suffered from strumous inflammation of the knee-joint. Abscesses formed, which remained open during many months, and which at length closed, leaving numerous cicatrices.

I found the leg flexed at an acute angle; the tibia slightly displaced backwards; the knee-joint covered with cicatrices, some of which were adherent to the patella, and some to the spine of the tibia; just appreciable motion of the joint existed; the patella was not ankylosed.

I divided the hamstring muscles, portions of tense fascia, and the adherent cicatrices, and a week afterwards I commenced to extend the limb gradually by means of an apparatus which had been made for that purpose. The limb, however, was only slightly straightened by this gradual extension, and as the adhesions appeared to be very firm and unyielding, I proposed to rupture them by the application of a suddenly imposed force. Before this was done, however, I sought the advice of my colleague, the late Mr. Lonsdale. Mr. Lonsdale thought, that as a last resource, rupture might be had recourse to; but before he sanctioned it, he was desirous of seeing that nothing more could be gained by gradual extension. This having been proved beyond doubt, the patient was placed under the influence of chloroform, the tendons, fascia, and cicatrices having been again subcutaneously divided eight days previously, and the leg was forcibly flexed upon the thigh. The adhesions were wholly fibrous, but exceedingly solid and tough, and it required the application of considerable power, and at the same time nice management of the skin, to effect the rupture of the first, and to prevent that of the latter. They yielded, however, with a tearing sensation. The limb was then again placed in the splint at the same angle as before. Some pain followed the rupture of the adhesions, but it was entirely allayed on applying cold to the joint. The patient slept well, without an opiate that night, and pain was not complained of, but tenderness only, afterwards. On the third day slight extension was made, and from this time it was continued as rapidly as it could be borne, until at the expiration of two months the limb was perfectly extended. Chloroform was again administered, and the leg was flexed freely. Some pain and swelling succeeded, but this condition of the limb was rapidly removed on the application of cold, and on the eighth day passive motion was commenced, and it was subsequently repeated each day to the utmost extent that could be borne. At length the limb could be flexed to a right angle, and it could be perfectly extended. Flexion of the limb to this extent caused considerable pain, however, so that the patient himself was unable to move the leg to a right angle. Notwithstanding, he enjoyed a range of motion which he could employ unassisted, and which was more than sufficient for the ordinary movements in walking. When this amount of freedom of the joint had been gained, Mr. Lonsdale again saw my patient, and he in consequence determined to adopt the same mode of treatment whenever he might have an opportunity. He subsequently broke down some adhesions in the manner

above-mentioned. The first operation in this case was performed in April, 1854; the second at the end of August of the same year.

In 1856, I again had an opportunity of examining the limb. It had increased much in size; the muscles of the thigh and of the leg were much larger than formerly, though the limb was still considerably smaller than the other. The motion of the joint had diminished somewhat in extent, yet useful motion remained. A stick for support was only used when he left the house.

#### PARTIAL ANCHYLOSIS OF THE ANKLE-JOINT.

*Case 8.*—E. O., 6 years of age, 1857. Nearly two years before this time the ankle-joint became much inflamed, the inflammation assuming a rheumatic character, and following a slight sprain. The inflammation continued some weeks, then abated, and it recurred. At length the joint became stiff, and fixed at a right angle.

February, 1857.—I found the leg slightly shorter, and the foot rather smaller, than the other; all the tendons around the joint prominent, and the foot firmly fixed at a right angle, with entire absence of pain and of power of motion. The tendons being tense, was evidence that ankylosis was not bony. I therefore divided them; namely, the tendo-Achillis, the tibiales, anticus and posticus, and the extensor longus digitorum, on February 26; and, four days later, as the Péronee remained very tense, I also divided them.

March 4.—On suddenly extending the foot the adhesions were torn through. This was not followed by inflammation, and there was scarcely tenderness of the limb after twenty-four hours. A Scarpa's shoe, with apparatus for exercising the various movements of the foot at the ankle-joint, was afterwards applied. Flexion and extension were, of course, the movements which it was most important to gain; and these, as well as slight power of abduction of the foot, were, to a great extent, gained by the end of May. At this time extreme extension and flexion caused pain, but all motion less than the extreme normal motion of the joint was painless. With an additional thickness of sole to her boot, the child could walk across the room, slightly favouring that foot, but without limping. Strength was gradually acquired, and also the size of the limb increased. The child wore a support for the ankle during many months, and wearing it there was scarcely an appreciable halt in the gait.

#### PARTIAL ANCHYLOSIS OF THE ELBOW.

*Case 9.*—S. D., aged 8 years, 1856. When he was three years of age he was jerked up from the floor by his nurse, who held him by the wrist. Acute pain at the elbow followed this act of violence, and inflammation succeeded, which terminated in loss of motion.

November.—I found the forearm slightly flexed, and the hand in a semi-prone position; the limb somewhat smaller than the other, and the elbow stiff and immovable.

November 22.—I administered chloroform and attempted to flex the arm. In this, however, I did not immediately succeed, but on continuing my endeavours the joint gradually yielded, without imparting a distinct sensation of tearing, until the arm could be fully flexed and extended. The radius, however, could not be rotated; and, although a prolonged effort was made for this purpose, it was useless. The arm was therefore enveloped in a wet bandage, and placed in a splint, at the same angle as before the operation. An inconsiderable amount of pain was suffered after the rupture. The patient slept well, and without an opiate, during the night; and on the following day the joint was not painful, except when pressure was made upon it.

November 24.—The forearm was moved upon the arm slightly, without exciting pain, and these movements were continued on alternate days, until November 29, when he was again placed under the influence of chloroform. Now, the radius could be rotated perfectly, and with very slight effort, the adhesions yielding immediately. Cold was again applied to relieve pain, and the arm was encased as before. No inflammation followed. After some few days passive motion was recommended, and in a very short time the arm could be perfectly flexed, and it could also be extended almost to a normal degree. Two months after the adhesions had been ruptured, there was considerable power of voluntary motion, which increased after this time, so that the forearm could be flexed beyond a right angle with the arm. Also there was a limited power of pronation and supination.

*Case 10.*—E. S., 11 years of age, November, 1855. Three years ago she fell and struck her elbow. Much pain and swelling followed, and the joint continued swollen and painful during many months. At length it remained stiff and immovable.

I found the entire limb somewhat diminished in size, the forearm slightly bent, and the elbow stiff and motionless. There was neither enlargement of the ends of the bones, nor thickening about the joint; or this existed to a very slight extent. And there could be no doubt that the adhesions which prevented motion were fibrous. Consequently, I proposed to rupture them, and carried this into effect November 12. They gave way instantly, on applying force, with a crackling sound. Some pain followed the rupture, and the next day slight effusion was observed about the joint. This, however, had entirely subsided on the third day. Gentle motion was then borne without complaint, and it was continued until the eighth day, when extended movements were again made. Some tenderness of the joint followed, which necessitated quiet for some days. Increased weakness was for a time felt, but motion was both more free and caused less pain. Passive motion was continued assiduously, and at the end of three months the movements of flexion and extension were almost perfect, and the power of motion existed to a considerable extent. She could now carry a spoon to her mouth with her right hand, which she had not previously been able to do. Power of motion was gained slowly; indeed, the progress was so gradual, that I almost despaired of permanent benefit being derived; yet, after a year and a half of unwearied attention, a very useful joint was gained.

I have again called attention to this subject for several reasons; both because forcible extension is used where it is not justifiable, and also because the greatest uncertainty seems to prevail as to the class of cases for which it is proposed.

Among other instances of forcible extension to which I have lately been a witness, was one of a contracted knee in a state of inflammation. The joint was acutely painful and swollen. The hamstring tendons were divided, and immediately, while the wounds were gaping, the limb was extended. It could not be fully straightened even by much force; but in this condition it was bound to a straight splint. It need scarcely be said that this extension could not be borne, and that the splint had to be removed. And further, it need scarcely be said that this violence caused a complication of evils infinitely greater than the contraction which it was intended to remove. This limb, which was lost by the force used, might have been most easily straightened by gradual extension after inflammation had been overcome.

Again, the following may be read in the *Lancet* of March 13, 1858, p. 265:—"Ankylosis of the Elbow-joint.—On the 11th February, a young man in University College, with extensive disease of the right elbow, was to have had the joint excised; but he was so low from unsuspected latent phthisis, that the operation was abandoned, and he died three or four days afterwards. On the 18th of the same month the same operation was to have been performed upon the elbow of a lad in the above Hospital, whose joint was ankylosed in a faulty position, being perfectly straight. The arm was quite useless to the poor boy, as he could do nothing with it, and it prevented him from earning a livelihood. He had had disease of the joint for eight years, which originated in a fracture. The arm was in a flexed position for four or five years; but, as he was in the habit of lifting heavy weights with it, it became gradually straight, and remained in that position, in a state of almost complete ankylosis; there was, however, a very little motion in the joint. No appearance of disease was manifest externally, and pronation and supination were perfect. It was an illustration of one of the class of cases in which excision is quite justifiable, namely, ankylosis in a faulty position. However, it was determined to try flexion under chloroform first; and this perfectly succeeded, as the adhesions were only fibrous, and the forearm moved freely on the arm. This was a gratifying result; and we may add that the boy is going on well, and will have capital motion in the joint."

Now, making allowance for any errors of description, here is an instance, well and forcibly recorded (I may say two instances), of that *furor* which at present prevails for the excision of articular surfaces. In the first, the patient died of phthisis three or four days after that on which resection was to have been performed. The second "was an illustra-

tion of one of the class of cases in which excision is quite justifiable. No appearance of disease was manifest externally, and pronation and supination were perfect." However, before proceeding to resection, it was determined to flex the elbow forcibly, when, wonderful to relate, the fibrous adhesions yielded, the forearm moved freely on the arm, and the boy "will have capital motion in the joint."

Comment is unnecessary. If any excuse were required for again bringing this subject under the notice of the Profession, it is to be found in the few preceding lines.

But it may perhaps be urged, that these cases are incorrectly reported. Of this I know nothing. But this I do know, that these cases do not stand alone, but that other "illustrations" might be added where excision was thought to be quite justifiable, but where, on opening the joint, it was found to be healthy. Three such instances of resection I could reveal. Also, of the thirty-two cases above alluded to, it had been proposed to remove the articular surfaces in three instances. In two of these cases, the limbs are now straight but stiff; in the third, very useful motion of the joint has been restored. It would be idle to assert formally, that a limb is more useful where the adhesions have been ruptured, and it remains straight though stiff (the knee for instance), than where resection has been performed, for the proposition cannot be denied. But when resection is proposed and practised, the joint being in such a condition as to admit of the restoration of motion, not only may it be said that such an operation is not justifiable, but that it is barbarous.

Again, it is said by some, gradual extension is safer than rupture of the adhesions. To which proposition I give my cordial assent. There is a class of cases, however, in which gradual extension of adhesions is utterly impracticable, in which it is never attempted, or if attempted, it cannot but fail; a class of cases which has been held to be incurable, except by resection. It is to this class that I would refer my remarks. Not only is it impossible that these adhesions should be overcome by gradual extension, even though the most carefully constructed apparatus be employed, but the restoration of motion has never been sought for, and could not possibly be obtained, without first rupturing the adhesions.

20, Grosvenor-street, Grosvenor-square.

## A CRITICAL SKETCH OF MR. TOYNBEE'S CONTRIBUTIONS TO AURAL SURGERY.

By WILLIAM KRAMER, M.D.

THE conviction, that "the pathology of the ear had been almost entirely neglected," induced Mr. Toynbee, in 1839, to commence a series of dissections of that organ, the results of which were published by him in two large groups (see *London Medico-Chirurgical Transactions*, for 1849 and 1855), and have lately been reprinted, with some additions, in a separate volume, under the title of "A descriptive Catalogue of Preparations illustrative of the Diseases of the Ear," 1857.

I have already, on some other occasions (see *London Medical Times and Gazette*, 1852, October 16), so fully discussed the little pathological value of the two former groups, that I should think it superfluous to add another word—even with reference to Mr. Toynbee's latest publication, in which, to the former dissections, amounting to 1523, only 136 new ones have been added, of the same character—if that treatise did not contain two things which it is impossible to pass over unnoticed.

In the first instance, Mr. Toynbee has, very unfairly, claimed for himself "the abolition of the terms 'otitis' and 'otorrhœa,' and the substitution of names indicating the tissue affected, and the peculiar nature of this affection;" whereas this question had been completely settled by me long before Mr. Toynbee appeared in public as an author;—a circumstance which could not have been unknown to that gentleman. (See my "Diseases of the Ear," translated by Mr. Bennett. London: 1837, pages 94, 96, 106, 129, 136.)

Secondly, Mr. Toynbee has called "the establishment of the existence, as a disease, of membranous and ossaceous

anchylosis of the stapes to the fenestra ovalis, one of the most common causes of deafness," which, from the contents of his own book, can be proved to be utterly groundless.

Mr. Toynbee expresses "the hope, that his dissections will be regarded as a solid basis, on which ultimately a complete system of Aural Pathology may be reared." Indeed, the imposing number of "1659 dissections" seems at once to justify that hope; it is, however, rendered more than doubtful by the author's way of proceeding with those dissections, as well as by the undeniable truth, that the pathology of the organ of hearing can only be promoted by dissections, if it be proved that the dissected ears have really been deaf, and have not only been examined during lifetime by means of appropriate instruments, but also properly treated, and the course of their illness closely watched to the last.

Out of the 1659 dissected ears, there are only 495, contained in the Catalogue, which Mr. Toynbee knew, from hear-say, to have been deaf. Of the remaining 1164 he had no notice whatever as to their having been actually deaf. Thus the result of the dissection of this by far greater number is of no value whatever, with regard to the pathology of the organ of hearing.

Mr. Toynbee never saw or examined a single ear, while living, out of the 1659; he did not establish, in a single case, the diagnosis of the probable change of organization, nor correct or confirm it by his dissections; he never entered upon a treatment; in short, his book contains nothing whatever that might turn the result of all those dissections into use for the pathology of the organ of hearing.

This startling contrast between the claims of science and the performance of the author, is the more inexplicable, as, on a former occasion (see *London Medico-Chirurgical Transactions*, 1855, p. 1), he mentions, among the number of 608 dissected ears, in the first place, "134 ears of deaf persons seen and examined by myself during life-time;" and he says of that class, "they have much higher value than the others." Mr. Toynbee, it is true, did not publish at that time a single one of those "examinations during life-time," apologising in vain for this omission; but now, not even this principle—quite true in itself—of the importance of careful examination of dissected ears during life-time, has been followed up in the Catalogue. The first series there only contains 272 diseased ears of deaf persons, "the history of whose cases was known to me [Mr. T.]" One instance will suffice to show the trifling benefit science will derive from those "histories of cases."

No. 512. "Male, aged 48. Deaf for about five years before death; could hear a shout on the right side, no sound at all on the left. The deafness commenced during a very severe ulceration of the throat after syphilis;"—statements in no way, either pathogenetically or diagnostically connected with the result of the dissection, viz., "stapes of both ears completely ankylosed; the membrane of the fenestra rotunda thickened, the cochlea of a deep-red colour (right ear); the membranous vestibule thickened (left ear)."

These results of dissection, "with histories," quite useless in themselves, but of great importance in the eyes of Mr. Toynbee, have not even been given entire—272;—only the fourth part of them—66 have been published in the Catalogue. The same unjustifiable deficiency occurs in other occasions of equal importance. Thus, in the "tabular view," 1149 diseased ears are mentioned, and yet only in 856 cases we read a more or less detailed description of the result of dissection; 293 are entirely omitted. The age of the bodies from which those 856 ears had been taken, is only given in 292 cases; in 564 instances it is not mentioned at all—an omission, which seems the more inexcusable, as there are already 143 ears (50%) out of those 292, which belonged to persons past 60,—an age at which auro-medical assistance is the less frequently sought, as it cannot be effectually rendered. Nay, Mr. Toynbee has not even, in every particular instance, mentioned the fatal disease of the persons from which those 856 ears are taken. It has been done in 87 cases only (10%),—the rest have been omitted, which again considerably lessens the value of the result of dissection for pathological purposes. The persons whose ears had been sent to Mr. Toynbee by his Medical friends for dissection, had died of "typhus fever, consumption, dropsy, pneumonia, scarlatina, measles, arthritis, scrofula, gangrene, apoplexy, diseased liver, and similar diseases (see *Medico-Chirurgical Transactions*, 1849, p. 76), which generally cause all sorts of morbid vegetative process in and on the mucous membrane, and, doubtless, also in that

of the organ of hearing. Under these circumstances, it remains uncertain whether the changes of organization observed by Mr. Toynbee in 1149 diseased ears, really existed as the basis of deafness, and especially how far they existed before the fatal disease, or whether they were not altogether unconnected with the deafness, and rather caused by the fatal disease.

Much for the same reason, the dissections contained in the Catalogue cannot be admitted as proofs for Mr. Toynbee's assertion, that "the membranous and osseous ankylosis of the stapes to the fenestra ovalis is one of the most common causes of deafness." After all, this assertion, being an hypothesis in no way proved, might be entirely passed over, as Mr. Toynbee did not, even in a single instance, diagnosticate the existence of this ankylosis of the stapes, nor in a single dissection show that the ankylosis was the cause of the deafness. Nevertheless, it would be a great pity not to make use of numerous other proofs the Catalogue contains against Mr. Toynbee and his hypothesis. We shall, therefore, conscientiously do so in the following lines:—

Mr. Toynbee, in his "Tabular View of the Morbid Appearances found in 1149 Diseased Ears," gives—

The base of the stapes ankylosed by bone to the fenestra ovalis	62
The base of the stapes ankylosed by bone, the base b. expanded	10
The base of the stapes ankylosed by membrane	43
The base of the stapes ankylosed by membrane, the base expanded	7
Ditto, ditto, an exostosis surrounding the fenestra	3
The base of the stapes attached to the fenestra ovalis more rigidly than natural	82
Ditto, ditto, the base expanded and fixed more rigidly than natural	7

214

(i.e., 20%, out of 1149); without, however, mentioning the organic condition which, in 89 cases, without "being osseous or membranous ankylosis," connected the base of the stapes to the fenestra ovalis "more rigidly than natural." It is not likely that Mr. Toynbee meant it implicitly to be "mucous membrane of tympanum thick," or "membranous bands of adhesion," as in the dissections belonging to the first rubric (Nos. 288—388 of the Catalogue), the stapes is often called "concealed," but not "more rigidly fixed than natural," and in the dissections belonging to the second rubric (Nos. 340—400), the stapes is called "less movable, more rigidly fixed than natural;" in five cases only, Nos. 345—348, and 399; and even in those cases that circumstance is not attributed to "the adhesions of the stapes to the promontory." Accordingly we should have to deduct those 89 cases from the number of Mr. Toynbee's ankyloses, as not proved, and thus the latter would be reduced to 126 cases out of "1149 diseased" ears (=11%, instead of 20%).

Now, if we turn from this reduction required by science, to the details given by Mr. Toynbee of the ankylosis of the stapes which he considers so highly important, it is perfectly clear that for the sake of this supposed importance, he ought to have minutely described all those 214 cases, and not only part of them—176, (Nos. 16, 17, 19, 53, 95, 98, 107, 135, 139, 150, 152, 163, 177, 191, 216, 399, 453, 489, 489a, 492—546, 548—578, 580—627a., 639, 645—653, 664, 665, 731, 732, 759, 760, 777, 779, 784, 785). Amongst the 38 he has omitted, there may have been some particularly interesting ones!

Amongst the 176 detailed cases of ankylosis of the stapes there are 75. (Nos. 19, 53, 95, 107, 399, 453, 492, 493, 501, 6, 7—10, 13, 17, 18, 20, 21, 24—27, 30—37, 42, 43, 46—51, 55, 56, 59—64, 604a.—8, 10, 11, 13—19, 22, 24, 25, 27a., 639, 48, 49a., 52, 53, 64, 65, 73, 732), nearly the half, in which Mr. Toynbee leaves us in doubt as to the ears having been deaf; thus they do not prove anything at all as to deafness being caused by ankylosis of the stapes.

Those 176 ankyloses include, moreover, no less than 104 ears, with considerable organic complications, which will never allow the ankylosis of the stapes to be considered as the sole, or even principal cause of deafness. In order to make this clear, I shall give a number of those complications. There were, besides ankylosis in No. 19, membrana tympani atrophied,

malleus partly destroyed, labyrinth very thick and opaque. 53.—The inner half of the meatus occupied by a moluscous tumour; the membrana tympani pressed inwards, so that its inner surface was in contact with the whole outer surface of the meatus. 95.—The membrana tympani is very thick and white, the tympanum contains mucus, its lining membrane is thickened. 152.—Membrana tympani, all the laminae thick. 163.—The membranous labyrinth was of a dark colour, the laminae spirales too, and covered by a dark soft substance. 191.—Membrana tympani very thick, fallen in and adherent to the promontory, the tympanic cavity being nearly obliterated. Lamina spiralis of the cochlea very thick. 216.—Membrana tympani partially destroyed by ulceration, fallen in and adherent to the inner wall of the tympanum. The membrane of the fenestra rotunda greatly thickened, and of dark colour. 453.—Membrana tympani much thicker than natural, mucous membrane lining the tympanum thick; the cavity contained mucus. 489 a. —The tympanum contained thick, white, and viscid mucus, the membrana tympani and mucous membrane of the tympanum were thicker than natural.—495. Posterior two-thirds destroyed by ulceration; what remains (of the membrana tympani) is in a state of ossific degeneration; the mucous membrane of the tympanum is much thickened. The membranous labyrinth is much atrophied, and its peculiar fluids deficient in quantity. 499.—The membrana tympani is almost entirely destroyed, the mucous membrane of the tympanum is dark-coloured and much thickened. In a very similar condition were the Nos. 504, 5, 6, 7, 8, 12, 19, 28, 29, 37, 40, 41: in this latter case the membranous vestibule and the nerve were atrophied. 544.—Membrana tympani destroyed, the inferior extremity of the incus is absent, so that it does not articulate with the stapes; mucous membrane of the tympanum thick. 545.—Membrana tympani very thick, and quite hard; the upper half is firmly adherent to the promontory; the tympanum is nearly full of the same calcareous matter into which the membrana tympani is converted. A similar condition of the parts concerned in Nos. 554, 55—58, 67—71. 578.—The membranous labyrinth was atrophied, the nervous filaments on the surface of the lamina spiralis were not distinct, and appeared to be undergoing fatty degeneration. Similarly in Nos. 581, 592—94, 606, 12, 13, 20, 21, 46, 89, 731, 32.—The posterior semicircular canal is incomplete, its posterior wall being deficient for an extent of about three lines. The membranous labyrinth and cochlea contained black pigment. 759, 60.—The membrane of the fenestra rotunda is ossified, and covered by a deposit of osseous matter; the vestibule and cochlea contained a sanguineous fluid; mucous membrana of the tympanum thicker than natural. 777.—The auditory nerve atrophied, the membranous labyrinth atrophied, like in Nos. 778, 79, 84, 85.

Those 104 complicated cases must therefore be deducted from the 176 detailed ankyloses of the stapes, if the question is to find out the causal connexion between ankylosis and deafness; accordingly there remain only 72 cases (Nos. 17, 177, 492, 93, 97, 98, 500—5, 10, 14—18, 20, 21, 24—27, 30, 36, 36, 38, 39, 42, 43, 46, 48—51, 61—64, 76, 80, 84—87, 90, 91, 601—604 a., 606, 608—11, 14—19, 23, 27a., 47, 48, 52, 53, 64, 66), which, with their isolated ankylosis of the stapes, might be used as proofs for the correctness of Mr. Toynbee's theory. But here again, in 45 instances (Nos. 492, 93, 501, 10, 17, 18, 20, 21, 24—27, 30, 35, 36, 42, 43, 46, 48, 49, 50, 51, 60—64, 604, 4a., 6, 8, 10, 11, 14—19, 22, 27a., 48, 52, 53, 64, 66), we do not find any notice whatever as to the ears having really been deaf! Thus, from 214 ears with ankylosis of the stapes to the fenestra ovalis, there remain but 27, (Nos. 17, 177, 497, 98, 500, 502—5, 14—16, 38, 39, 76, 80, 84—87, 90, 91, 601, 2, 3, 9, 47), whose isolated ankylosis might have caused deafness, if the age of the persons from which those ears had been taken was not decidedly against it. Only one (No. 647) out of that number was 20 years old; two (497—498) had reached the age of 30; one (500) that of 40; two (502, 3), that of 50; two (584, 85) of 60; four (177, 504, 5, 76), of 70; ten (17, 514, 15, 38, 39, 90, 91, 601, 2, 3), of 80. In five cases (516, 80, 86, 87, 609), the age is not given at all.

Thus more than the half (16) of those isolated ankyloses were past sixty,—an age in which, to say the least, it is doubtful whether the ankylosis was the cause of the deafness, or whether both had not rather been caused by the advanced age of the patients.

This latter opinion will be materially corroborated by a

classification of the respective ages of the persons, from which those 133 ears with anchylosis of the stapes had been taken:—

One (No. 639) was in the age of . . . 5 years.

Three (Nos. 588, 89, 647) were . . . 20 "

Five (Nos. 495—98, 612) . . . 30 "

Four (Nos. 500, 12, 626, 27) . . . 40 "

Nine (Nos. 95, 139, 453, 94, 502, 3, 13, 759, 60) . . . 50 "

But 36 (Nos. 98, 135, 191, 492, 93, 99, 517, 18, 30, 31, 32, 35, 42—45, 50, 51, 59, 60, 62, 63, 83—85, 93, 94, 604, 22, 23, 25, 46, 49, 49a, 784, 85) had reached the age of . . . 60 "

43 (Nos. 150, 163, 177, 504, 5, 19, 26, 27, 33, 36, 46, 48, 49, 52—56, 61, 65—73, 76—78, 92, 97—600, 620, 21, 51, 177—79) . . . 70 "

30 (Nos. 10, 17, 53, 152, 511, 14, 15, 22, 23, 28, 29, 34, 38—41, 57, 58, 64, 74, 75, 81, 90, 91, 95, 96, 601, 2, 3, 50) . . . 80 "

2 (Nos. 731, 32) even passed that of . . . 90 "

Twenty-two only (one-fifth) were under sixty, and 111 (four-fifths) past sixty!

Now, this analysis of the materials contained in the "Catalogue" has been made with diplomatic accuracy: add to this the fact, that Mr. Toynbee, even in his lately published (see *London Medical Times and Gazette*, 1856, April 23—1867, April 27) "Lectures on the Diseases of the Ear," has not said a single word about the diagnostic, and the cure of the anchylosis of the stapes; and we consider ourselves fully justified in asserting, that he has utterly failed in proving, that "the anchylosis of the base of the stapes to the fenestra ovalis is one of the most common causes of deafness."

Berlin, June, 1858.

## GENTIAN TENTS

IN THE TREATMENT OF

### PARTIAL OCCLUSION OF THE CERVICAL CANAL OF THE UTERUS.

By J. H. AVELING, M.D.

Member of the Royal College of Surgeons, London, Hon. Member of the Obstetric Societies of Edinburgh and Dublin, etc.

THE office of the cervical canal of the uterus is somewhat peculiar, inasmuch as it has to transmit two distinct fluids in two opposite directions. If any obstruction, therefore, exist in it, the ill effects are doublefold. If the semen is unable to reach the interior of the uterus, sterility is the consequence; and if the menstrual fluid is unable to pass into the vagina, amenorrhœa or dysmenorrhœa, if the obstruction be only partial, are the effects.

I propose now only to speak of those cases in which the cervical canal of the uterus is partially occluded, and shall at once proceed to glance over the numerous abnormal conditions which may give rise to it.

Partial occlusion of the cervical canal of the uterus may be (a) congenital; or it may be caused by (b) a membrane stretching across the canal, the result of adhesive inflammation; by (c) injuries during labour; by (d) hypertrophy and elongation of the neck; by (e) an inflamed and congested state of the mucous membrane lining the canal; by (f) polypi and excrescences lodging in the canal; by (g) a plug of viscid lymph filling up the canal (a); by (h) displacements of the uterus; by (i) cancer and tumours; by (k) spasmodic contraction; by (l) the injudicious employment of caustics, etc.

In looking over this list of causes, it is cheering to notice in how many the interference of the Surgeon would be likely to be advantageous. Of course, no one mode of treatment would cure all; and in bringing the plan of treatment which I shall presently mention before the Profession, I do not pretend to have found a universal remedy. The good effects of dilatation in these cases is now fully recognised. Women who have been sterile, and who have suffered all their lives

(a) "We have observed the whole cylinder of the canal of the cervix to be filled or tamponed, so to speak, with a plug of viscid lymph, so obstructing the passage as to render it apparently impossible that any spermzoon could obtain access to the uterine cavity."—Meigs on "Diseases of the Neck of the Uterus."—P. 56.

from dysmenorrhœa, have by its means ever after menstruated naturally, and often become mothers of large families. The question is not, whether dilatation shall be employed, but how.

It is certain that some look upon the mechanical treatment of dysmenorrhœa as a great fallacy. "The dilatation of the os uteri to increase the flow of the menses is a specimen of great credulity," says Campbell (b); and others who have attempted the operation without producing the desired effect are sceptical as to its value. I am inclined, however, to think that a great deal of this feeling has been produced by the selection of improper cases or by the incomplete way in which they have been treated. For instance, if the seat of stricture be at the os uteri internum as well as at the os externum (as is the case with a patient I have now under my care), little benefit would be obtained by dilating the os tincæ alone; or if it be a case of dysmenorrhœa, accompanied with large firm clots, no relief would be afforded by dilating the canal to such a size as would admit of the introduction of the sound.

The accumulation of the menstrual fluid, if the uterus be not very irritable, at first merely produces a feeling of weight in the loins and of distension in the pelvis. These, however, are soon followed by the most severe bearing-down pain, which is often so agonising as to bring the patient down upon her knees as if she were in labour. The perspiration streams down her face, and her sufferings are at length terminated by the expulsion of a clot which has actually been crushed through the strictured canal by the violence of the uterine contractions. Where these symptoms persist after the employment of the ordinary modes of treatment, an examination is peremptorily called for.

Professor Simpson's sound is of the greatest value in the diagnosis of these cases. By it we can find out the exact point or points of obstruction, and also the amount of distension of the cavity of the uterus which the accumulation of the fluid has caused. I cannot admit that the ease or difficulty with which the sound may be introduced into the uterine cavity is a sufficient test as to the necessity of operative interference. When the menstrual fluid is secreted slowly, and is thin and unaccompanied by "clots and shreds," an aperture through which the uterine sound would pass might probably be large enough to allow the fluid to flow without causing more than ordinary pain; but when the opposite is the case, I feel convinced that such an opening would be insufficient. The clot resting in the canal forms a perfect ball-valve, and relief can only be obtained by its being crushed, or by its gradually dilating, by a painful process, the whole length of the constricted canal before it. The os uteri, though it certainly does relax to a certain degree at the menstrual periods, is not so accommodating as some writers represent, who make it to open and shut like the mouth, whenever it is required (c). If the stricture be firm and the clot hard, nothing but the forcible dilatation of the former, or the crushing and breaking up of the latter can give relief. It is cruel to leave to nature the excruciating process of dilating the canal, when it can be almost painlessly performed by science.

Dilatation of the os uteri seems to have been performed as early as the days of Hippocrates (d), although still later, in the time of Fabricius at Aquapendente, obstructions of the os uteri were looked upon as incurable (e). Mauriceau fully recognised the effect of an obstructed condition of the cervical canal of the uterus in producing sterility and dysmenorrhœa (f), and mentions instruments for curing it (g). Dr.

(b) "System of Midwifery." Edit. 1843, p. 507.

(c) L'action par laquelle l'orifice interne s'ouvre et se ferme, suivant les différentes nécessités, est entièrement naturelle, et nullement volontaire, ce qui a été fait fort à propos; car si le mouvement de cet orifice dépendoit de la volonté des femmes, il y en a beaucoup, qui par ce moyen s'empêcheroient de concevoir, en usant du coït; et plusieurs seroient assez méchantes pour expulser et rejeter, quand elles voudroient, la semence qu'elles auroient conçue, afin de s'exempter des incommodités de la grossesse, et d'être toujours en état de satisfaire avec volupté au désir insatiable de cette partie, dont il est parlé dans l'Ecriture au 30 chap. du livre des Proverbes. "Tria sunt insatabilia . . . infernus, et os vulvæ et terra."—Mauriceau, p. 40.

(d) "When sterility is connected with the shutting up of the os uteri the author gives directions for expanding it by means of wooden or leaden pipes."—Adams' edition of the works of Hippocrates, vol. i. p. 111.

(e) "Præterita uteri orificium unitum incidi non potest propter situ alitudinem."—Edit. 1648, De Chirurgicis operatibus, p. 97.

(f) Observations sur les Maladies des Femmes Grosses, etc.—Ed. 1715, pt. ii. p. 434.

(g) Ibid. p. 423. "Des instrumens d'ivoire en forme de fuseaux."

Mackintosh was the first to bring this subject prominently before British practitioners. He published 27 cases in which he had dilated the uterine canal with bougies, and of these 24 were cured of dysmenorrhœa, and 11 became pregnant (h). This marvellous success at once attracted attention, and among those who now sanction and practise the operation of dilating the cervical canal, in some way or the other, may be mentioned the names of Professor Simpson, Dr. Oldham, Dr. Rigby, Protheroe Smith, Mr. Whitehead, Mr. I. Baker Brown, etc.

Professor Simpson uses metallic bougies of graduated sizes, or adopts the speedier method of dividing the stricture with a kind of lithotome caché (i). Dr. Rigby uses a dilator with blades of well-tempered steel, which are expanded within the cervical canal, and allowed to remain so for a short time (k). Mr. I. Baker Brown has adopted the tubular system, which Mr. Thomas Wakley employs in stricture of the urethra (l), and others prefer still to use the elastic bougies which Dr. Mackintosh first proposed.

The plan of treatment which I, with all modesty, now propose, appears to me to have advantages over the different contrivances which I have just mentioned. A piece of gentian root is easily obtained, and any one possessing a penknife can manufacture it into a tent of the required size. It may be readily introduced by the aid of a pair of common dressing forceps, without using the speculum. A piece of string should be tied to its vaginal extremity, for the purpose of removing it after it is expanded. In less than four-and-twenty hours the tent, by the absorption of the fluid with which it is in contact, will have dilated the canal as far as it is able. It may then be withdrawn, and another introduced of a larger size if necessary. In treating these cases, it must be remembered that the seat of stricture may be nearly two inches higher up than the os tincæ. The tents should therefore be two inches and a half long, at least, so as to ensure their penetrating the os uteri internum. I have been struck with these tents coming out marked deeply by the strictures. In one case, in which the stricture had been caused by the application of powerful caustics (m), the tent appeared as if it had been tightly constricted by a piece of fine cord. The discharge during the presence of the tent is, of course, of a brown colour. Injections of warm water should be frequently used.

Should there be a tendency in the strictures, after they have been dilated, again to contract, one of Professor Simpson's stem pessaries should be worn.

The gentian tent is cheap, simple, and efficacious. No other requirements can be sought for in an instrument.

My silence upon the constitutional treatment of these cases may lead some to think that I ignore it altogether; such is not the case; and I beg to refer those who wish good sound practical information upon this subject to Dr. Rigby's work, "On Female Diseases."

Sheffield, June 8, 1858.

## THE LONDON PRACTICE OF MEDICINE AND SURGERY.

### THE LONDON HOSPITAL.

#### CASE OF ONYCHIA MALIGNA, WITH LARGE FUNGOUS GROWTH FROM THE BONE.

(Under the care of Mr. ADAMS.)  
(Reported by Mr. GILL.)

According to the patient's own statement, this is the first time she ever remembers to have been laid by. Her general appearance certainly verifies her statement. About eighteen months ago, a very painful swelling attacked the second finger of the left hand, and soon went on to assume all the characters

of onychia. For this she attended as an out-patient at the Leeds Infirmary, where the nail was removed, and lotions of various kinds applied for about six weeks. Before this was properly cured, another appeared on the thumb. On this occasion she was made an in-patient, and remained there for eleven weeks, during which time the nail was removed, and caustics frequently applied. At the expiration of this period she was discharged, a fungous growth about two-thirds the size of a moderate-sized walnut, having arisen from the radial side of the thumb, and which, moreover, the Surgeon pronounced to be incurable. It is now about twelve months since she left Leeds, and during the whole of this long period nothing but wet cloths have been applied to the affected part.

At the time of her admission into the London Hospital, the nail of the second finger was turned upwards, and almost black, the finger generally having a very unhealthy appearance, and a fungous growth about the size of a small hen's egg was attached to the side of the thumb. It was extremely sensitive to the touch, and caused the patient a great amount of constant throbbing pain.

May 20.—The patient having been placed under the influence of chloroform, Mr. Adams proceeded to remove the tumour. As it was attached by a small base only, a single incision sufficed to do this. Mr. Adams expressed a hope that the bone was unaffected, but unfortunately finding that his hopes were disappointed, he dissected away the flesh, and removed the bone as far as the first joint. As the part was very vascular, it became necessary to secure several vessels. This being satisfactorily performed the opposed surfaces of the gaping wound were brought together by means of sutures, and the thumb bound up in dry lint, in order to restrain the general oozing which was still something considerable.

Mr. Adams then removed the nail of the second finger, and applied acid nit. fort. to the denuded part.

The patient throughout was on full diet, and wine 3x.

May 23.—At the patient's own request the wine was taken off, and an extra pint of porter substituted. She is doing very well indeed.

Upon making a section of the tumour after removal, it appeared to consist almost entirely of fibrous tissue.

## HOSPITAL NOTES.

### GONORRHOËAL INOCULATION FOR THE CURE OF OBSTINATE CASES OF PANNUS WITH GRANULAR LIDS.

Mr. Bowman the other day directed our attention to the case of a young man who had for long suffered from an extreme state of granular lids, with vascular opacity of the corneæ. Both eyes had been affected, and all ordinary measures of treatment had been exhausted upon them. The right had, however, at length been cured by the practice of gonorrhœal inoculation. The contrast between the two was most striking. In the right only a little dimness of parts of the cornea remained; there was no vascularity or irritability, and he could see to read the smallest print. The left, on the contrary, showed in bands of adhesion between the palpebral and ocular conjunctiva, the effects of over-stimulant treatment, while the cornea was still covered with a network of vessels, and the lids granular over their entire surfaces. Four months had elapsed since the inoculation, prior to which the right had been much the worse eye. The lad had now come most anxious that the same treatment should be adopted for the one from which he still suffered, and Mr. Bowman willingly acceded to his request. Of course we do not wish our readers to accept a single fact of this kind for more than it is worth, in support of so severe a measure of treatment. About six eyes are, we believe, all that have yet been subjected to it at the Moorfields Hospital, and we are not aware that it has ever been adopted at any other in London. In one of the cases both eyes were inoculated, and in the four others only one. Dr. Bäder, to whose hands the management of them has been deputed, informs us that in all these the final result has been most satisfactory, and that, although in several the artificial inflammation was most threatening for a time, yet in none was the cornea damaged. The only treatment adopted consisted in the application of ice to relieve pain, no lotions whatever being used. When only one eye was

(h) Practice of Physic, vol. ii.

(i) Obstetric Works, vol. i. p. 289.

(k) On Diseases of Women, p. 54.

(l) Medical Times and Gazette, Feb. 1857, p. 187.

(m) Speaking of caustics Mr. I. Baker Brown says, "I have had many cases come under my notice where partial occlusion of the os and cervix has been the result of their use; and I feel certain that the use of such agents is a more frequent cause of sterility than is generally supposed."—Medical Times and Gazette, Feb. 1857, p. 187.

treated, the other was bandaged to prevent any accidental inoculation. It is to be borne in mind that gonorrhoeal ophthalmia, occurring in a case of vascular cornea, is not nearly so dangerous as if the eye were previously sound. The worse the condition of pannus, and the more perfect the morbid vascular supply, the less is the risk of sloughing of the cornea. Indeed, if only very advanced cases be selected for this treatment, very little risk indeed is run (a).

#### INJECTION OF AN OVARIAN CYST WITH IODINE.

The following case has recently been treated by Mr. Bickersteth in the Liverpool Infirmary. A thin, spare widow woman, a cook, was admitted in January with an ovarian tumour. She had been tapped for the first time in the preceding September, having then known of the existence of the disease for seven months. On January 13 a second tapping was practised, sixteen quarts being drawn off, and six ounces of the tincture of iodine (Ph. Edin.) were injected, and allowed to remain. Not much disturbance followed. Iodine was detected in the urine, perspiration, etc. The sac refilled, and on January 30 it was again tapped, and the injection repeated. On this occasion eight ounces were left in. The tumour, however, again refilled, and she was sent into Wales for change of air. Subsequently she was again admitted, in order to obtain relief from her great distension. Paracentesis was done on May 2, and she recovered, and was about to leave the Hospital, when her health began rapidly to give way. She died shortly afterwards; but, unfortunately, no autopsy was permitted.

#### LAYING OPEN OF AN UMBILICAL HERNIA IN AN ATTEMPT AT SUICIDE.

A poor woman was admitted under Mr. McMurdo's care into St. Thomas's, about a fortnight ago, having attempted suicide by laying open a large umbilical hernia with a carving-knife. It appeared that she had in the first instance tried to cut her throat, but having succeeded only in stabbing herself through the crico-thyroid membrane, was dissatisfied with the result, and then resorted to the more formidable measure. She was aged about 50, and was very stout. The incision in the hernial tumour was large, and had laid bare a considerable mass of omentum. No intestine had been protruded, and the neck of the sac was so close that it would not anywhere admit the end of the finger. Most of the omentum was adherent, and had evidently been for long incarcerated; but a portion close to the neck of the sac had been recently extruded. The skin could not be made to cover the mass exposed, and the adhesions made any attempt at reduction out of the question. The House Surgeon accordingly contented himself with applying wet lint over the whole.

#### THE PROVINCIAL

#### PRACTICE OF MEDICINE AND SURGERY.

#### STATISTICAL REPORT OF THE PRINCIPAL OPERATIONS PERFORMED DURING THE YEAR 1857.

(Continued from page 577.)

THE subjoined Report comprises the following Hospitals:—Addenbrooke's (Cambridge), the Bristol General, the Cheltenham General, the Cumberland (Carlisle), the Derby General, the Dorset County (Dorchester), the Dundee Royal Infirmary, the Glasgow Royal, the Gloucester, the Hull, the Leeds, the Leicester General, the Liverpool Royal, the Liverpool Southern and Toxteth, the Queen's, Birmingham, the Sheffield General, the South Staffordshire (Wolverhampton), the Staffordshire General (Stafford), the Sussex County (Brighton), the West Norfolk and Lynn (Lynn), the York County.

#### OPERATIONS FOR THE REMOVAL OF MALIGNANT TUMOURS.

Case 1.—The West Norfolk: Dr. Cotton.—A woman, aged 55, was admitted with a large fungoid tumour, the size of an

(a) The inoculation plan was, we believe, first proposed by Dr. Henry Walker, in 1811. Dr. Piringer, of Gratz, and Jaeger, of Vienna, have been among its more recent advocates.

adult head, and growing from the left buttock. At the urgent request of the patient the tumour was excised, together with a large part of the glutæus maximus muscle, from the substance of which it grew. The wound had partly healed, when in about five weeks the disease returned. The patient now left the Hospital, and died in about three weeks afterwards.

Case 2.—The Leeds: Mr. Teale.—A healthy man, aged 44, the subject of epithelial cancer of the gum and lower jaw, about the position of the wisdom-tooth. A flap was raised from the cheek, and the tumour and the bone to which it was attached, freely excised. The parts quickly healed.

Case 3.—The Leeds: Mr. Hey.—A woman, aged 41, the subject of a large epithelial cancer of the right labium. Excision; recovery.

Case 4.—The Brighton: Mr. Turner.—A chimney-sweep, aged 30. Excision of a soot-cancer of the scrotum. Recovered.

Case 5.—The Dundee: Dr. Crockett.—A man, aged 25, apparently in good health, the subject of a large malignant tumour of the back, attached to the fascia of the spine. The tumour was excised; but not long afterwards the disease reappeared in the axilla, and he left the Hospital in a feeble and sinking condition.

Case 6.—The Liverpool Royal: Mr. Bickersteth.—A healthy-looking man, aged 50. A melanotic tumour, the size of an egg, was excised from beneath the angle of the jaw. Recovered.

Case 7.—The Liverpool Royal: Mr. Bickersteth.—A delicate woman, aged 24, the subject of recurrent fibroid tumour on the inner and upper part of one arm. The original growth, the size of a fist, had been excised twenty-one months previously, and a second nine months ago. On the present occasion, the tumour was about as large as an orange. A third excision was practised, and she again recovered well.

Case 8.—The North Staffordshire: Mr. Ball.—A man, aged 58, apparently in good health. Excision of a large malignant tumour from the side. Recovered, but before the wound had quite healed the disease returned.

Case 9.—The Leeds: Mr. Hey.—A healthy woman, aged 67, the subject of a recurring fibroid tumour in front of the elbow-joint. The growth had first appeared thirty-one years ago, and it had been four times previously removed (once by the knife, once by ligature, and twice by chloride of zinc).

Under the microscope it showed well-characterised recurrent fibroid structure.

Case 10.—The Leeds: Mr. Hey.—A healthy-looking man, aged 60, from the corner of whose mouth a well-marked epithelial cancer had been excised five months before. The recurrent growth in the cheek resembled encephaloid rather than epithelial structure, both to the naked eye and under the microscope. Recovered.

Case 11.—The Bristol General: Mr. Coe.—A woman, aged 54, was admitted with a large hard tumour beneath the glutei and pressing upon the sciatic nerve. It was excised, and proved to be cartilaginous in structure. Before the wound had quite healed the growth reappeared, and took on a malignant aspect.

A second excision was attempted, but found to be impracticable, and the patient died eight weeks afterwards. Secondary deposits of cancer were found in the mesenteric glands, in the lungs, liver, and kidneys.

Case 12.—The Brighton: The House Surgeon.—A woman, aged 40. Excision of a growth of soft cancer from the temple. It had been of six weeks' duration, and appeared to spring from the bone. It soon recurred, and the woman left the Hospital to die.

Case 13.—The Brighton: Mr. Turner.—A boy, aged 3. Excision of a large growth (14oz.) of soft cancer from the right side of the chest. It had been growing for six months. Under treatment.

Case 14.—The Leeds: Mr. Hey.—A stout girl, aged 20, had an encephaloid tumour about the size of a marble, developed in the substance of the upper lip. It was excised, and the parts united. The wound healed well, and there were no evidences of tendency to return.

Case 15.—The Royal Berkshire: Mr. May.—A chimney-sweep, aged 44, in good health, from whose scrotum a soot cancer had been excised two years and a-half ago. A recurrent growth, but on quite a different part of the scrotum, had existed for six months. Excision. Recovery.

Case 16.—The York: Mr. Hey.—A man, aged 71, excision of an epithelial cancer of the scrotum. Recovery.

Case 17.—Addenbrooke's: Mr. Humphry.—A woman, aged 65, in good health, excision from below the orbit of a warty epithelial cancer which involved the bone beneath. A portion of bone was removed. Recovered.

Case 18.—The Derby: Mr. Fearn.—A stout man, aged 53, the subject of a recurrent fibroid tumour on the back, which had been three times excised. A fourth excision. Recovery.

Case 19.—The Derby: Mr. Fearn.—A boy, aged 5, was

admitted with staphylocoma of the cornea. An amber-coloured cataract concealed the deeper parts of the eye. The staphylocoma was absceded, and the lens and part of the vitreous humour evacuated. The nature of the disease now revealed itself, and a large sprouting tumour was rapidly developed. A month after the first operation, it having attained the size of a small fist, it was excised. A month later, a recurrent growth was also removed. In about a fortnight the disease again showed itself, and at the date of report had attained the size of the child's head, and would, no doubt, soon prove fatal. *Case 20.*—The Derby: Mr. Fearn.—A man, aged 46. Excision from the groin of a large growth, partly encephaloid and in part melanotic. Recovery. *Case 21.*—The Dorset County: Mr. Tapp.—A healthy chimney-sweep, aged 59, excision of a soot cancer from the scrotum. Recovery. A cancer had been removed from his scrotum fourteen years before, and he had been wholly free from the disease until within the last two years and a-half. *Case 22.*—The York: Mr. Hey.—A chimney-sweep, aged 45, excision of almost the whole scrotum on account of soot cancer. The testes were necessarily laid bare, but the healing was rapid and most satisfactory.

In addition to the above, there remain nine cases of epithelial cancer of the lip, which we may save space by grouping together. All the patients were men. Their ages were respectively 28, 50, 54, 56, 60, 62, 65, 66, and 79. In seven the lower lip was the one affected, and in two (aged 28 and 79) the upper. In one case almost the whole lip had to be excised. In all the cases the wounds healed well.

The reader will find many other cases illustrating the Surgery of Cancer in other parts of this report, as for instance, forty-one under the head of "Tumours of Breast" and others under those of "Amputations," "Removal of the Testis," "Excision of the Upper Jaw," "Amputation of the Penis," etc., etc.

#### EXCISION OF THE UPPER JAW.

*Case 1.*—The Leeds Hospital: Mr. Teale.—A woman, aged 22, was admitted with a large fibrous tumour, developed within the right upper maxillary bone, and encroaching also upon the left. Excision of the whole right bone was performed, a considerable portion of the left being also removed. She sank exhausted, and died on the following day. *Case 2.*—The Queen's Hospital, Birmingham: Mr. Langston Parker.—A woman, aged 55, the subject of malignant disease of the right upper maxilla. Excision of almost the whole bone was performed on April 29th. A good recovery resulted, and at the date of report there was no evidence of tendency to return of the disease. The disease filled the cavity of the antrum.

#### OPERATIONS FOR TUMOURS OF THE BREAST.

Excision of the mammary gland, or of tumours imbedded in it, appears to have been performed during the year in 51 cases. Of these five were cases of mammary glandular tumour ("Adenocoele" of Mr. Birkett), the ages of the patients being respectively 17, 23, 26, 28, and 36. In none of these was more than the tumour itself removed, and in none was the latter of unusual size. Four cases presented examples of "Cystic tumours of the breast," the patients being aged 43, 46, 48, and 50 respectively. These were probably midway in point of malignancy, between adenocoele and cancer, being structurally much more nearly allied to the former. In a single case, in which the patient was aged 48, the tumour is stated to have been "medullary carcinoma." In 38 cases the entire gland, or almost the whole of it, was removed on account of the ordinary scirrhus cancer. Of these, the patients were of the following ages, 27 one, 32 one, 34 one, 35 two, 36 one, 39 two, 40 one, 41 two, 43 one, 44 one, 45 one, 46 two, 47 three, 48 one, 49 two, 50 six, 52 two, 53 one, 57 two, 60 three, 62 one, 64 one. The whole of these 48 cases ended in recovery, as far as the operation was concerned.

The following are additional to the above, and are given in abstract on account of their either having ended fatally, and from their presenting features of unusual interest:—

*Case 49.*—The Leicester: Mr. Paget.—A woman, aged 28, in excellent health, a tumour had been growing for six years in her right breast, about two inches to the inner side, and a little below the nipple. An incision was made along its side, and with a few touches of the scalpel enucleation was easily effected. Dr. Sloane (H.S.) describes it as a calcareous

tumour, and states that it was of stony hardness, of irregular exterior, and about the size and shape of a small fig. The wound healed well. *Case 50.*—The Glasgow. A woman, aged 30. Excision of the breast on account of scirrhus. Death from scarlet fever. *Case 51.*—The Dorset County: Mr. Tapp.—A woman, in tolerable health, aged 64. A growth of hard cancer, the size of a chestnut, existed in one breast, and had been noticed for more than two years. It was excised, and the wound did well up to the fourth day, when a slight blush of erysipelas attacked it. This passed off, but she remained feeble, and without appetite. After a while one wrist-joint swelled, and then both legs became oedematous, and there was swelling about one ankle-joint. No fluctuation was ever detected in either joint. Stimulants and quinine were freely used, but on the 20th day, whilst taking her dinner, she suddenly became much worse, and died in about half an hour. No autopsy was permitted.

## Medical Times & Gazette.

SATURDAY, JUNE 26.

#### TOWN AND RURAL HOSPITALS.

A measure has been lately carried out to a small extent in Paris, which is well worthy of imitation in London and to a larger extent—the removal of Hospitals and Poor-houses from thickly-populated town districts to more airy suburban situations. Although the difficulty of such a change looks at first sight formidable, we are convinced of its necessity and ultimate application. As a financial scheme the matter must be viewed in two lights: first, in regard to the existing Hospitals, and secondly, in reference to the construction of new Hospitals, or rather we should say, of Hospitals which have no representative at the present time. The old Hospitals, encumbered with certain trusts and endowments, might find a transfer embarrassing. But Hospital founders having to begin *de novo* would secure, in a suburban position, many advantages even in a pecuniary point of view.

But independently of the mere matter of economy, the subject demands earnest consideration on much sounder and nobler grounds. In the presence of the sanitary facts of the day, in the presence of the fact that the Hospital is really and truly intended for the cure of the sick, and lastly, in the presence of the notoriously painful fact that Hospitals situated in the heart of dense populations, despite all the aid gratuitously afforded by the most learned of the Medical body, do not carry out this intention to one half the extent they might, nor relieve the mortality bill even of its units—in presence of these facts we say, it behoves us, as wishing well for the fair fame of Medicine, that the great impediments to curative success, long acknowledged as part and parcel of the present Hospital system, should be carefully investigated and promptly removed.

An opinion has recently been gaining ground, that Hospitals for certain special diseases have no business to have any existence whatever. Or, at all events, if they are to exist, that they require to be entirely reformed in relation to pos-

tion and construction. But the argument admits of wider application. We believe that the day will come, nay, is at hand, when the very idea of confining within four walls a multitude of human beings suffering from any disease, will be looked on as one of the lunacies of science, and as verifying the triumphant art of nourishing disease by that on which it is fed. The fact is now day by day being realized, that diseases of various types may be experimentally produced by bad air; and even the public are beginning to understand why disease is rife in barracks and in workhouses, in densely-populated streets, and in all human dens where human beings are herded, and human breaths commingled.

We have referred to Hospitals especially, not invidiously, but because they exhibit more than other large establishments certain public evils. The general Hospital in the dense neighbourhood takes an active share in these evils. You may ventilate this general Hospital, give the seventeen hundred cubic feet of space to each bed, provide special wards, admit light, and unquestionably mitigate much evil, and diminish mortality. True, these improvements have been done, and more in this direction will be done. But the labour is only half-way towards the success which might be secured; inasmuch as no efficiency of construction can ever make amends for error in position.

In our present state of knowledge regarding the statistics of Hospitals, we must speak with great caution, for here a great statistical question lies open for inquiry. Meantime there are some facts collected by Dr. Farr, which show that the prospects of the sick in large cities are not such as could be wished for, either by Philanthropist or Physician.

In the following table, for instance, Dr. Farr has shown the relative mortalities of certain rural and town Hospitals:—

FOUR RURAL HOSPITALS.

HOSPITALS.	In-Patients treated in One Year.	Mean Number of In-Patients.	Deaths.	Deaths out of 100 Patients.	Deaths in 36 Days out of 100 Patients.
Salop . . . 4 years, 1880-83	965	92	84	3.7	3.6
Winchester 1 year, 1833-34	798	83	81	3.8	3.7
Salisbury 1 year, 1833-4	894	88	27	3.1	3.1
Chester . . 2 years, 1833-5	489	45	20	4.2	4.5

FOUR CITY HOSPITALS.

HOSPITALS.	In-Patients treated in One Year.	Mean Number of In-Patients.	Deaths.	Deaths out of 100 Patients.	Deaths in 36 Days out of 100 Patients.
Manchester 1 year, 1831-2	1,784	138	125	7.2	10.0
Liverpool 1 year, 1831	1,900	220	109	5.0	5.0
Bristol 1 year, 1828-9	1,483	195	160	9.5	8.2
London 7 Hospitals . . .	18,740	2,191	1,605	9.0	7.6

There is, then, in so far as these records go, an immense difference in the mortality of the rural and town Hospital. The deaths in the Rural Hospital vary from 3 to 4 per cent., the deaths in the City Hospital from 5 to 9 per cent., and Dr. Farr adds, "These observations are in conformity with what is seen in other Hospitals."

In considering the above table, one or two points deserve attention. These are, firstly, that the size of the Hospital makes a difference in the mortality, the mortality seeming to be much higher in larger Hospitals than smaller ones; and, secondly, that the types of the diseases met with in the city and in the rural Hospital differ materially. In the thickly populated city, the patients drafted into the sick ward enter with but half the gift of life. They often sink rapidly after operation, and show, at best, in comparison with their country neighbours, but the shadow of endurance. But these facts, however much they may soften down the statistic's dismal figures, do not by any means account for the whole difference of the reckoning. If we would look without bias into the mortality of the City Hospital, we shall find it in the Hospital endemic visitations—in those visitations of erysipelas and pyæmia especially, which often for weeks at a time so alarm the conscientious Surgeon, that

the knife is to him even a more cruel terror than to the patient on whom the knife should do its skillful office.

Apart, however, from the dangers of the pests of City Hospitals, the high mortality of these Hospitals must be contemplated. We may fall back, indeed, on the argument already quoted, relating to the class of people who fill our large City Hospitals, and bring forward their case in absolute support of the view that the City Hospital system has been carried so far, that its furtherance were a shame and a delusion in the present day. Because the occupant of the wards of the Urban Hospital is physically degraded to a lower standard than his country brother, so is it the more necessary, when disease makes him its prey, that his removal from those influences which have produced his physical degradation should be the basis of those remedial means which are to meet and remove his disease.

We could say much more in favour of the plea for establishing Rural Hospitals for our great towns and cities; but we must remain content, for the present, with an attempt to urge the immediate practical importance of the measure. Immense sums are being raised for the enlargement of King's College Hospital. But we very much question the propriety of expending these large sums in adding to this already extensive building in the densely crowded district on which the present Hospital stands. It is certainly necessary to have a central receptacle for cases of accident and acute disease, and clinical wards for the instruction of Medical students; but Hospitals are erected for the welfare of the sick, and no one can deny that nine out of ten of the inmates of our large London Hospitals would be infinitely better off in some airy suburban situation. The Council of King's College have the opportunity of setting a good example by expending the funds they are so liberally entrusted with by the charitable public in the erection of a rural sanatorium, into which they may draft the patients from their City Hospital. Plenty of pure fresh air is what is wanted to reduce the mortality of our large Hospitals. It cannot be had amid the smoke and dust, the poisonous gases poured from thousands of sewers into our streets through innumerable gully holes, the reeking of house drains into ward or bedroom, the combined exhalations of more than two million human beings and countless quadrupeds, and the miasms evolved from the mighty sewer into which our ignorance or indolence has converted our noble river. It is positive cruelty to submit sick men, sick women, sick children, to such a tainted atmosphere without the plea of pressing necessity. It is an equally positive duty to attempt to diminish the evils inseparably dependent on the existence and increase of large Hospitals in large cities.

## THE WEEK.

There was rather a numerous attendance of Medical men at the House of Commons on Tuesday, anxious to hear the discussion on the committal of Mr. Cowper's Bill. But the affair passed off amid a few inaudible mutterings from Mr. Headlam, Colonel French, and Mr. Walpole, it having been arranged that certain proposed amendments should be printed and the Bill as amended considered next Thursday at 12 o'clock. The principal amendments relate to the mode of electing the Council and the definition of its powers. Mr. Cowper has submitted to the correction of some of the obvious defects in his original measure, but we very much question whether any one thinks well enough of the Bill, even as amended, to carry it through Parliament by the aid of lukewarm friends in the face of earnest opposition. The other Medico-parliamentary matters of the week have related to the state of the Thames, Chancery Lunatics, New Barracks, Coroners' Inquests, and Netley Hospital. The Legislators are nearly stunk out of their own house, yet they are not even able to decide if the necessary works should be paid for by the nation

or by local rates.—It is not disputed that Chancery lunatics—551 in number—are badly treated. It is admitted that there are only two Medical men to inspect these 550 lunatics scattered all over the country, and that the salary of these inspectors is only £500 a-year. But inquiry is postponed on the promise that next year the Government and the Lord Chancellor will not oppose a full inquiry into the working of the Act of 1853. The inquiry is much needed, and we trust that it will be complete.—The Chancellor of the Exchequer refused to move the Portman Barracks to any part of the Kensington Gore estate, because the land was sold on the stipulation that no buildings should be erected on it of an "offensive character." Why our soldiers should be condemned to buildings of an "offensive character" the Minister did not explain.—Nor would he submit to the appointment of a committee on the Law and Practice of Inquests and Remuneration of Coroners, because it would "lead to a long discussion."—Sir F. Smith and General Peel defended the site and construction of Netley Hospital; and we may conclude that further opposition will cease.

Mr. Sands Cox has been elected Principal of Queen's College, Birmingham. As Mr. Cox is the founder of two most important institutions, this appointment is a most satisfactory one, and we feel convinced it will lead to progressive improvements in the College and increased success.

The "Thames" is becoming so unbearable that every one is crying out, "Something must be done!" A jury returned a verdict, in an undoubted case of cholera, "That the deceased died from the effect of an attack of Asiatic cholera, brought on by inhaling the noxious vapour of the Thames." And the Board of Health says:—"From the 'Dreadnought,' it is stated, by the resident Medical officer, that 'during the last week the effluvia from the Thames water has been of the most sickening character, and, from its depressing action on myself and other officers, it must be obnoxious to the well-doing of the patients. We have had two deaths from typhus fever, and a third case in great danger.' The propriety of retaining such a site for a hospital would appear to require investigation. In the Royal Marine Infirmary, Woolwich, it is reported 'that there are now seven cases of diphtheria, all doing well; likewise in the department for women and children this disease is becoming prevalent.' People are being poisoned by fetid miasma from the river, and the only wonder is, that some fearful epidemic has not decimated the inhabitants of the Metropolis; yet, while everybody is dissatisfied, nobody acts. We must have the banks of the river so covered that no mud is exposed at low water, and all the sewage must be intercepted. We cannot be satisfied with less than this. "No mud, and clean water," is the cry. A million, more or less, will not be grudged if the work be well done.

A memorial has been addressed to the Lord-Advocate of Scotland by the College of Physicians of Edinburgh, showing that in the amended edition of the Bill for improving the Scotch Universities, the existing holders of Medical Degrees would be almost entirely excluded from voting for members of the University Court; while clergymen of all denominations, and others who have gone through a purely literary course of study, would be entitled to a vote, whether possessing the degree of M.A. or not. It is added very justly:—"That the College is not aware of any inferiority in the social or educational status of the Medical Profession which would justify this invidious exclusion—that the College believes the welfare of the Universities, not less than that of the

Medical Profession, to be concerned in maintaining for the Medical graduates a position corresponding to their important functions, and their character as men of education—that the Medical graduates of the Scottish Universities undergo more rigid examinations, and pursue a course of study more varied and extensive than those required for any other profession; and that their virtual exclusion, under these circumstances, from the government of the Universities, is alike indefensible and unjust." The Lord-Advocate can hardly refuse to introduce into the Bill amendments calculated to relieve Medical graduates from the unmerited exclusion which they will suffer according to the Bill as it at present stands.

We have received from the Early Closing Association a pamphlet containing some practical testimonies to the benefits attending the early weekly payment of wages, and we are anxious to express our own sentiments as to the beneficial effects likely to follow, in a hygienic point, the general adoption of the system of paying wages on some other day than Saturday. It is found that when the last day of the week is the period selected, the workman is tempted by the next day's holiday to spend a great part of his earnings in intoxicating drinks, to the great detriment of his health as well as his morals; while, on the other hand, the purchase of all kinds of necessaries is made on the Sunday; thus greatly increasing the evils of Sunday-trading, and preventing the shopkeepers and their assistants from enjoying the rest which their health demands on one day of the week. There needs no argument to prove the degradation of mind and the train of physical evils induced by the too free indulgence in intoxicating drinks; it is almost equally needless to insist that the workman and the shopkeeper are alike entitled to one day in seven as a period of rest; and we therefore hope that employers will be generally induced to alter the present prevailing system of paying wages on the Saturday night. The pamphlet published by the Early Closing Association contains a long list of public companies and private firms which have adopted the plan of paying their workmen on Friday, or on some earlier day in the week, and the innovation seems to have worked most beneficially. For the change proposed there is every argument which charity and true philanthropy can suggest: in opposition to it there is really no argument whatever. We, therefore, hope that reason and good sense will prevail in causing the general adoption of so beneficial a change.

The medico-legal points raised in the case of Sir Henry Menz require some remarks. The question for the jury was the state of Sir Henry's mind on the 3rd of July, 1857, when he wrote instructions for a *codicil* to a will made nearly a year before. Between the making of the will and the *codicil*, Sir Henry had a severe fit—in December, 1856,—when Drs. Watson, Ferguson, Williams, and Sir Benjamin Brodie, were consulted. They then pronounced that there was softening of the brain. The speech, and gait, and mind were already affected. All through 1857 (to September) we have conflicting evidence—1. Of incapacity throughout the canvassing for Hertfordshire, and of utter inability to command his troop of yeomanry at a review. 2. Of capacity to transact all kinds of business. In September, 1857, there was another fit, and then *all* allow he became insane. Nevertheless, there were business transactions afterward. Dr. Conolly's evidence and opinion were, that he first saw Sir Henry on January 22, 1858. He was in a most advanced stage of "general paralysis," so advanced a stage that the Doctor thought the malady must have commenced a year and a-half or two years before. He never saw a recent case so far advanced. He never knew the peculiar speech and gait seen and described *without* the insanity; never

knew them *precede* the mental disorder, although they supervened often in mania of long standing; in other cases, the speech, gait, and mind, are *simultaneously* affected. He believed the malady, "general paralysis," began in December, 1856. Its peculiar character is so little known, except to asylum doctors, that it is assumed to be common paralysis, which is *not* necessarily associated with mental disorder. But the question which puzzled the jury was this: Was Sir Henry's mind *so far* affected in July, 1857, as to render him incapable of judging soundly as to a codicil? in other words, Was he of "disposing mind?" This nobody can tell, except those who may not wish to tell the truth. The opinion that his judgment was then seriously impaired, rests on experience of the distinct and peculiar malady with which beyond doubt he was already affected, in an *advanced* stage of which Dr. Conolly found him in January, 1858, and in the last stage of which he is at present. But this opinion can be no guide to the jury. The case may even have been exceptional. But that the "general paralysis" began in 1856, and has gone on steadily ever since, is, so far as we can learn from the evidence, the real fact.

Medical officers are participating, in a manner very creditable to the Government, in the decoration of the Victoria Cross. Very lately we were glad to see that it was conferred on Deputy-Inspector Mount, C.B., for having voluntarily proceeded to the assistance of Colonel Morris, who was lying dangerously wounded, in an exposed situation, after the retreat of the light Cavalry from their fatal charge at Balaklava, and for having dressed that officer's wounds under a heavy fire from the Russians. We have now very great pleasure in extracting the following records of Medical heroism from the last *Gazette*:—

"78th Regiment.—Assistant-Surgeon Valentine Munbee M'Maser; date of act of bravery, 25th of September, 1857. For the intrepidity with which he exposed himself to the fire of the enemy in bringing in and attending to the wounded on the 25th of September, at Lucknow.

"90th Regiment.—Surgeon Anthony Dickson Home; date of act of bravery, 26th of September, 1857. For persevering bravery and admirable conduct in charge of the wounded men left behind the column, when the troops under the late Major-General Havelock forced their way into the Residency of Lucknow, on the 26th of September, 1857. The escort left with the wounded had, by casualties, been reduced to a few stragglers, and being entirely separated from the column, this small party, with the wounded, were forced into a house, in which they defended themselves till it was set on fire. They then retreated to a shed a few yards from it, and in this place continued to defend themselves for more than twenty-two hours, till relieved. At last, only six men and Mr. Home remained to fire. Of four officers who were with the party, all were badly wounded, and three are since dead. The conduct of the defence, during the latter part of the time, devolved, therefore, on Mr. Home, and to his active exertions previously to being forced into the house, and his good conduct throughout, the safety of any of the wounded and the successful defence is mainly to be attributed.

"90th Regiment.—Assistant-Surgeon William Bradshaw; date of act of bravery, 26th of September, 1857. For intrepidity and good conduct when ordered, with Surgeon Home, 90th Regiment, to remove the wounded men left behind the column that forced its way into the Residency of Lucknow, on the 26th of September, 1857. The dooly bearers had left the doolies, but, by great exertions, and notwithstanding the close proximity of the Sepoys, Surgeon Home and Assistant-Surgeon Bradshaw got some of the bearers together, and Assistant-Surgeon Bradshaw, with about 200 doolies, becoming separated from the rest of the party, succeeded in reaching the Residency in safety by the river bank."

The old spirit of military exclusiveness is evidently dying out, or acts such as these would still be passed over with the silence and neglect which proved so galling to Naval and Military Surgeons in days gone by.

A small blue book has just made its appearance, containing a preliminary Report of the Commissioners appointed to inquire into the best mode of distributing the Sewage of Towns, and applying it to beneficial and profitable uses. The great difficulties of disposing of the excrementitious matters of large towns, and at the same time of avoiding the pollution of rivers, have long been admitted, and it is clear that the difficulties increase with the increase of the population. Fully admitting the purifying influence of flowing streams, of atmospheric oxygen, and of aquatic animal and vegetable life, upon the products of human and other excrements, it is plain that there is an increasing amount of impurity collecting in the river Thames, which does endanger the health of the population living upon its banks. For the double purpose, therefore, of diverting the refuse matter from the Thames and other large rivers, and throwing it where it is imperatively demanded—upon the fields, the Commission has been appointed, of which the first Report is now before us. The subject is so wide and so important, and is at the same time so beset with difficulties, that we can merely glance at some of the questions discussed by the Commissioners. The high value of animal manure in fertilizing the earth, is not for a moment to be denied; but it is a law of nature that the decomposing matters, which are all-important to the vegetable world, are noxious to human health; and therefore any scheme of evaporating sewage-water so as to obtain a solid and fertilizing residue must be attended with the utmost danger in a sanitary point of view. The Commissioners, amidst these difficulties, propose a kind of middle course, and they suggest that sewage matter may be rendered serviceable in three methods to the land: first, by irrigating the soil by sewage matter very largely diluted, as is done in the Edinburgh meadows and in the rice-fields in the vicinity of Milan; secondly, by collecting the fluid manure and distributing it over the land by means of pumps and jets; and thirdly, by precipitating the solid matter of sewage by means of lime, which, besides the separation of the precipitate, also acts by neutralizing in part the noxious gases which sewage water contains. An Appendix to the Report contains a very interesting account of the system of irrigation pursued in the plains of Lombardy, in the vicinity of Milan; but it must be mentioned that the rice-fields are kept at the distance of four miles from the capital. The Report also contains suggestions for a scheme for draining the metropolis, the chief features consisting in the construction of large and elevated terraces on the banks of the Thames, acting as so many reservoirs for the sewage, which is to be pumped out at intervals, and if not utilized for the land, is to be discharged into the river below low-water mark. This scheme appears to us to be very faulty; and we trust that no plan will be attempted to be carried out, which does not provide for complete interception of all sewage matter from the river.

A case of poisoning by nicotine has just occurred under very painful circumstances. Mr. Witt, a gentleman associated with Dr. Hofmann, at the Royal College of Chemistry, and favourably known as a chemist of rising reputation, has destroyed himself by taking a quantity of this formidable poison. From the evidence given at the inquest, held on Tuesday last, it appeared that the deceased had for some time been in a desponding state of mind, and that he had laboured under groundless delusions respecting his position and circumstances. On the morning of Saturday, the 19th inst., he was seen by one of the attendants at the Museum in Jermyn-street, in the act of falling forwards out of a water-closet in which he had concealed himself. The attendant raised him up, and with the aid of another man endeavoured to carry him to a table, but he died in their arms,

heaving one deep sigh. They noticed a peculiar smell, and on searching the water-closet they found a stoppered bottle containing a brown liquid, which when examined by Dr. Hofmann proved to be nicotine,—the alkaloidal poison of tobacco. The quantity of poison taken by the deceased is unknown; but the bottle had a capacity of about six drachms, and there was about half-a-drachm to a drachm remaining in it when found. The deceased must have taken the nicotine just before he was seen by the attendant, as this poison operates with the greatest rapidity, and destroys life in from two to five minutes. The only observation regarding the symptoms is, that he became suddenly unconscious, and lost all power of moving. The eyes were prominent and staring; there were no convulsions of the limbs. Dr. Wilson, who saw the body in ten minutes after death, stated that there was a slight clenching of the fingers on the palms of the hands; but otherwise a general relaxation of the muscles. He noticed a remarkable fulness about the neck, and a bloated state of the features. The principal appearances were, great congestion of the membranes of the brain, with a dark and fluid state of the blood. The stomach and contents, with parts of the other viscera, have been placed in the hands of Dr. Alfred Taylor for chemical examination. This investigation is rather for the purposes of science, than to throw any light on the cause of death, which was clear enough from the circumstances. The jury, upon the evidence, gave a verdict to the effect that deceased had destroyed himself by taking nicotine while in a state of temporary insanity. This is the first case of death from nicotine that has taken place in this country, and the second which is to be found recorded in the annals of science. Some of our readers may remember that the Count Bocarmé was tried at the Assizes of Hainault, in Belgium, in 1861, for the murder of his brother-in-law, Gustav. Fougues, by poisoning him with nicotine. The prisoner had made a special study of chemistry for the purpose of procuring this poison. He took an opportunity of forcing a quantity of it down the throat of Fougues, in his dining-room at the Castle of Bitremont, in the presence of the Countess Bocarmé, the deceased's sister, who was tried as an accessory to the murder. The Count was convicted and executed. Fougues died in five minutes. The quantity of poison administered was unknown; but six grains of nicotine were extracted from the contents of the stomach, by M. Stus, the Belgian chemist. An attempt had been made to destroy the strong and peculiar odour of the poison, by pouring acetic acid over the body after death; but this piece of diabolical ingenuity did not defeat the chemical investigation. The odour of nicotine, although most powerful, appears to be rapidly lost; for in the case of Mr. Witt it was not perceptible sixty hours after death, when the inspection was made. The great heat of the weather may, in some measure, account for this fact.

## REVIEWS.

*A Manual of Psychological Medicine, containing the History, Nosology, Description, Statistics, Diagnosis, Pathology, and Treatment of Insanity. With an Appendix of Cases. By JOHN CARLISLE BUCKNILL, M.D., and DANIEL H. TUKE, M.D. Pp. 562. London: 1858.*

THIS very valuable contribution to Psychological Medicine is the joint production of two gentlemen who have already gained a high reputation in the literature of insanity, and in the treatment of the insane. With regard to the portions which each has respectively contributed, we are informed in the Preface that the chapters on the History, Nosology, Description, and Statistics, constituting about the first half of the book, are written by Dr. Tuke; and the rest, including the Diagnosis, Pathology, and Treatment of Insanity, with the Appendix of Cases, are by Dr. Bucknill. The latter gentleman is the well-known editor of the *Asylum Journal*, and is the Medical

Superintendent of the Devon County Lunatic Asylum; and Dr. Tuke, who is a direct descendant of William Tuke of York, the earliest of English reformers in the treatment of the insane, is the author of a prize essay on Insanity, and is the Visiting Medical Officer of the York Retreat. Both of these gentlemen, therefore, have a claim to attention on the ground of their psychological antecedents.

Dr. Tuke commences with a short sketch of the opinions entertained by the ancients on the subject of insanity, and of the treatment which they recommended; and he shows that madness must have been well known in early times, not only from the actual occurrence of this malady among the historical personages who figure in the pages of the sacred and profane writers, but also from the frequent use of insanity made by the poets to heighten the effect of their imaginary conceptions.

In the third chapter, Dr. Tuke passes on to estimate the bearings of modern civilization on mental disease. The conclusion is, as might be expected, that man, in his social, refined, and polished condition is more liable to a disturbance of his mental faculties than when he was in the savage state. The explanation of this apparently anomalous conclusion is that, in a state of progressive advancement in intellectual and moral culture, man has more faculties to disturb. The immunity from insanity possessed by the brute creation, and by the savage races of mankind, depends upon the fact that their intellectual powers are reduced to their lowest state, even if they can be said to exist at all. This explanation, however, does not embrace the whole case; and there can be no doubt that we are ourselves responsible for much of the oversensibility of our own brains. Excessive head-work, forced education, the abuse of stimulants, the eagerness to acquire money, perverted notions of religion, are but a few of the agencies of modern days which tend to disturb the balance of the intellectual powers, and to fill our lunatic asylums.

The fourth chapter treats of the amelioration of the condition of the insane in modern times, especially in regard to mechanical restraints. This is a part of the subject with which Mr. Tuke is especially familiar, and the sentiments now expressed are, we believe, almost exactly the same as those of his Prize Essay published a few years ago.

The classification adopted in this Manual does not present any particularly striking features, nor does it pretend to accomplish the hitherto impossible task of separating from one another by well-marked lines of distinction, the ever-varying shades of mental alienation. It commences with the condition where the mental powers are either absent or reduced to their lowest state, as in idiocy, including cretinism and imbecility; the next form being dementia, in which the reasoning faculties are lost; then comes delusional insanity, when just conclusions are formed from premises which are unsound, and where morbid thoughts often eventuate in dangerous actions; the next is emotional insanity, including melancholia; and the last, in which the mind is most violently disturbed, is Mania, in its acute and chronic forms.

The allotment of the topics of the Manual to the respective authors appears to us to have been very judicious, and the subjects introduced are exceedingly well suited to the style of writing and the mental habits of each, which evidently differ considerably. In the first portion of the book, written by Dr. Tuke, we find repeated evidence of research and of logical accuracy of thought,—qualities eminently required of an author who deals in the details of the history, statistics, and classification of a given malady; and we have no doubt that his summaries and conclusions will carry great weight with the Profession.

The chapters on the diagnosis, pathology, and treatment of insanity are by Dr. Bucknill, and they are characterised by sound judgment, founded on extensive reading and practical experience. There is an entire absence of any wish to dogmatise, or to propose startling novelties; and Dr. Bucknill executes the task allotted to him in the spirit of a man who feels the enormous difficulties of the subject he is treating, and the necessity of regarding it in every possible light before arriving at conclusions.

The diagnosis of insanity is difficult enough; for although the discrimination of physical diseases, attended with derangement of the intellect, may be within the scope of every Physician's powers, yet who shall determine with absolute precision the boundaries which distinguish sanity from insanity of mind, or fix the exact period when the healthy balance of the mental powers has been disturbed? If insanity were a positive

entity; appreciable to the senses, some fixed and invariable laws as to its existence might be laid down; but the Physician who pronounces upon the mental soundness or unsoundness of his fellow-creature is only one finite being judging of the intellectual condition of another, having only his own fallible intelligence as the standard of comparison. If, again, we seek to give precision to our diagnosis by reference to physical symptoms, or by the comparison of post-mortem revelations, our difficulties multiply instead of diminishing; for the very connexion of mind with matter cannot be visibly demonstrated, still less can the aberrations of the one be definitely proved to have a measurable relation with the morbid appearances of the other. The dissection of innumerable brains has hitherto led to very little in the way of definite results, although it has contributed a multitude of loosely recorded facts, together with many erroneous conclusions; and not a few of the most distinguished psychological authorities have abandoned in despair the attempt to explain the phenomena of insanity by reference to morbid anatomy. Dr. Bucknill, in the treatment of this very complicated and difficult subject, shows much sound sense, practical experience, and just reasoning; and all must admit that his views are entitled to the most careful attention, even where the reader may not be wholly convinced by the force of his arguments. A good analysis of what is known of the connexion between the morbid manifestations of the mind with the pathological changes in the brain will be found in Dr. Bucknill's pages, together with some original matter of his own, which has thrown considerable light on this mysterious question.

Our limits will not permit us to follow in detail a number of other topics suggested by the perusal of Drs. Bucknill and Tuke's Manual. We can only add that the section on Treatment is as valuable as any other part of the work, and may be safely taken as a guide by all those who are engaged in the management of the insane.

The Manual supplies a want which has long been felt, and it will no doubt be long regarded as a standard work on psychological medicine.

## GENERAL CORRESPONDENCE.

### ON THE TREATMENT OF SCARLATINA WITH TINCTURE OF IRON.

LETTER FROM R. H. MEADE, Esq.

[To the Editor of the Medical Times and Gazette.]

SIR,—The treatment of the severer forms of scarlet fever is acknowledged to be often most unsatisfactory; and I see by a late number of the *Medical Times and Gazette*, in which the supposed efficacy of both ammonia and acetic acid in this disease are alluded to, that attempts are being made to bring forward some remedy that may prove more successful than those in general use.

During the last eight or nine months scarlatina has been very prevalent in this neighbourhood, and in some localities very fatal. My attention having been thus directed to the disease, I have been particularly struck by the close resemblance between many of its symptoms and those of erysipelas (a), and I determined to treat it in the same manner.

I had long been convinced of the value of the tonic and stimulant treatment in all forms of the latter disease, and formerly placed my chief confidence in ammonia: I found, however, that the mineral acids with quinine were more efficacious, and generally prescribed them, until a few years back, when the tincture of sesquichloride of iron was recommended. Though the value of this remedy has been doubted, I have found it so useful, that I regard it almost as a specific, both in the idiopathic and traumatic forms of the disease; and invariably prescribe it both in hospital and private practice; and I have been assured by other Medical men that they have equal faith in its virtues.

Having so much confidence, therefore, in the tincture of

iron in erysipelas, I determined to try it in scarlatina, and I have, accordingly, given it during the last winter and spring to every case that I have seen, with the exception of a few, which were so slight as scarcely to require any medicine. The success of this treatment has exceeded my expectations, and I have only had one fatal case since I commenced its use. Several cases, in which the symptoms set in with severity, were apparently cut short by it; and almost all the cases in which I gave it recovered with unusual rapidity. I give it in doses varying from five to fifteen minims, according to the age of the patient, every three or four hours; and when the throat is ulcerated I also apply a solution of nitrate of silver to the fauces. Several of my Medical friends have tried the tincture of iron at my suggestion, and have reported favourably of its use.

I know that it requires a much more extended experience before the peculiar efficacy of this remedy can be established; and the principal motive that I have in bringing it before the Profession is to induce others to give it a trial.

I am, &c. R. H. MEADE, F.R.C.S.

Sen. Surgeon to the Bradford Infirmary.

Bradford, April 18, 1858.

### SECONDARY HÆMORRHAGE IN WOUNDS OF THE HAND.

LETTER FROM DR. FREDERICK J. LOWES.

[To the Editor of the Medical Times and Gazette.]

SIR,—On the 8th of August, 1857, I was summoned hastily to a man reported to be bleeding profusely from the hand. On my arrival at the house he was in I found him quite blanched, and very faint. I ascertained that, ten days before, the middle finger of the left hand had been crushed, whilst he was engaged in pile-driving. He at once presented himself at the Portsmouth Hospital, where his finger was amputated at the junction of the metacarpus with the phalanx, and he was made an out-patient, the artery having been secured by a ligature, which had come away, and been followed by secondary hæmorrhage. I remained with him some time (the bleeding having ceased before my arrival, and there being no return of it); I plugged the wound, and left him. He progressed very favourably till the following Wednesday, when I was again summoned to him in haste, in consequence of a return of hæmorrhage. I decided that the only plan would be to tie one or both of the arteries of the forearm. I immediately cut down on the radial, and secured it; but the bleeding being as profuse as ever, I placed another ligature round the ulnar artery, which effectually stopped the blood. He now went on very well, the hand being kept warm, and the wound assumed a healthy appearance, when on the following Sunday week, eleven days after, I was again summoned to him, as the blood was pouring from the wound. I found that both ligatures had come away, that both arteries had no pulsation, and were impervious, and concluded that the blood was conveyed by the anastomosing branches. I placed a tourniquet on the brachial artery in the upper third of its course, and determined to cut down on the brachial just below it; this checked the hæmorrhage, but did not altogether suppress it for nearly three quarters of an hour. I then left him with my assistant, directing him to apply the tourniquet if necessary. The result proved satisfactory, for the wound healed kindly, the ligature came away on the thirteenth day, without any return of hæmorrhage, and the circulation was ably carried on by the recurrent branch of the radial, and the man went back into Wiltshire cured.

The most extraordinary feature in this case was the second attack of hæmorrhage coming on, simultaneously with the separation of the ligatures from the radial and ulnar arteries, when both those vessels were impervious; and as the circulation must have been carried on by anastomosing branches, why did not the hæmorrhage return before that time? as of course the separation of the ligatures from those two arteries could not have been the cause of the return of it.

I am, &c.

FREDERICK J. LOWES, M.D., F.R.C.S.

Anglesey, Llants,  
June 16, 1858.

(a) I am aware that there is no novelty in this fact, some pathologists thinking that a most intimate connexion exists between the *materies morbi* in these and some other acute contagious diseases. (See Dr. Holland's *Medical Notes and Reflections*.)

# ASPHYXIA FROM THE ADMINISTRATION OF CHLOROFORM, AND THE "MARSHALL HALL METHOD."

LETTER FROM GEO. WIGAN, ESQ.

[To the Editor of the Medical Times and Gazette.]

SIR,—Having been requested by a patient to administer chloroform, in order to have an examination made of disease of the neck of the bladder and prostate (the parts being extremely sensitive to pain), assisted by a Medical friend, I applied it in the usual way. In three or four minutes the patient's breathing became suddenly very much accelerated. Chloroform was discontinued. Speedily the pulse at the wrist ceased. No pulsation of the heart to be felt; and, lastly, respiration was not in the slightest degree perceptible. My friend exclaimed the startling words, "He is gone!" and I felt the full force of it in these times of inquests. I impulsively turned him on his belly (apparently lifeless), immediately and forcibly set up the rotatory motion as advised by Dr. Marshall Hall, and in two minutes (very long ones to us) there were signs of animation, and he soon recovered.

I have administered chloroform in some hundred of cases, even to children a few weeks old, and never saw the slightest untoward symptom; and in the above case I am convinced that no stimulant could have availed, and the recovery was entirely due to the discovery by that great physiologist Dr. Marshall Hall.

I am, &c.

GEO. WIGAN, M.R.C.S. Eng.

West Maitland, New S. Wales, April, 1858.

## REPORTS OF SOCIETIES.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JUNE 8, 1858.

Sir C. Locock, Bart. President, in the chair.

A communication by Dr. A. B. GARROD was read, entitled  
RESEARCHES ON GOUT.

The author divided his communication into two parts: in the first were detailed the results of his analyses of the urine in the different forms of gout; the second was devoted to the consideration of the influence of the different forms of colchicum upon the urinary secretion. After describing the method of analysis employed in arriving at his results, and speaking of the opinions usually held upon the subject of the urine in gout, Dr. Garrod proceeded with the first part of his paper, the cases in which he subdivided into three classes.

1st Class.—Cases of acute gout, occurring in patients most of whom in the intervals of the attacks enjoyed pretty good health. About thirty analyses for uric acid made on the twenty-four hours' urine of several different patients were detailed, and a few for the determination of urea; and from these the following deductions were drawn. In the earlier stages of acute gout, the urine, for the most part, is small in quantity, and the uric acid, measured by the twenty-four hours' secretion, diminished; that this acid is thrown out in much larger quantities as the disease becomes mitigated, and that these amounts, even above the patient's daily average, may be passed, forming sometimes critical discharges; and, lastly, the acid again becomes lessened, although not to the extent which occurs either just before or at the commencement of an attack. That the urea is usually thrown out in about the normal quantities, although its free elimination by the kidneys is often somewhat impeded, and, in consequence, the blood contains a small excess, which may possibly explain, in some measure, one peculiarity of gouty inflammation when it attacks superficial parts—namely, the presence of œdema and the subsequent desquamation of the cuticle. That occasionally a trace of albumen exists in the urine, but very seldom, compared with its occurrence in the chronic forms of the affection. 2nd Class included cases of chronic gout, the majority of which were not suffering from any urgent symptoms, but were afflicted with some of the sequelæ of the

affection, as shown by the concretions of urate of soda upon different parts of the body, and the stiffened condition of the joints. More than sixty analyses for uric acid were given in this class, made upon the day's urine of fourteen different individuals, and numerous determinations of urea were also detailed. The deductions from these observations may be thus summed up:—The urine in chronic gout is usually rather pale in colour, below the average tint in the healthy subject, of low density, and increased in quantity. The amount of urea, except in extreme cases, the same as in health (due account being taken of the diet of the patient at the time the urine passed). The uric acid was very much diminished indeed, and subject to excretion in very varied quantities at different times; and, lastly, the presence of a small amount of albumen is exceedingly frequent. Deposits in the urine are not of common occurrence in these subjects; but they occasionally occur on the cooling of the fluid, sometimes in the form of urate of soda or ammonia, at other times crystallized and more or less coloured rhombs of uric acid. Class 3.—Urine of individuals who had suffered more or less frequently from attacks of acute gout, of varying degrees of intensity, examined at the time of complete freedom from any symptoms of the disease. Several determinations were made on the urine of six individuals, and the following results arrived at: In no one of the six patients' urine did the amount of uric acid reach the quantity usually considered to be the average in health; in most of them it was far below, and it would appear that the kidneys in such individuals are apt to lose some of their excretory power for this body,—a circumstance which must necessarily render the blood impure, and account for the liability which such patients possess to periodic visitations of this malady, and the great difficulty of effecting a radical cure of the disease.

Part 2.—Devoted to an examination of the influence of colchicum upon the urine. The usual opinions held by different authorities, as Christison, Chelius, etc., upon the *modus operandi* of this drug were first related, and many of the analyses brought forward in their support were shown to be very fallacious, the error arising not from any fault in the analyses themselves, but from small specimens of urine, passed at particular times of the day, being examined, and no account taken of the twenty-four hours' elimination. Between fifty and sixty analyses, showing the amount of the uric acid eliminated, were given, together with numerous determinations of the urea. The results of these observations on the action of colchicum were as follows:—In one case, where no gouty affection existed, and no febrile disturbance was present, colchicum appeared to have the effect of slightly diminishing the quantity of urine, and likewise of diminishing somewhat the excretion of uric acid. In a second case, similar to the above, the influence of the medicine was notably to diminish the quantity of urine, the uric acid being slightly increased, but the increase was less than a quarter of a grain per diem. In case 3, a gouty patient recovering from an acute attack, the uric acid was somewhat increased during the administration of colchicum, but not in a greater degree than frequently occurs under such circumstances when no medicine is given. In case 4, both the urine and the uric acid were diminished by the influence of the drug; and so on for the other cases. The author considered, as the results of his analyses—1st. That there is no evidence to prove that colchicum produces its effects upon the system by causing the kidneys to excrete an increased amount of uric acid, but that, in fact, the reverse would seem to hold good. 2nd. That colchicum is not always a diuretic, but often diminishes the renal secretion, especially when its action is exerted upon the alimentary canal. 3rd. That colchicum has no marked influence on the excretion of urea. An appendix to the paper contained the results of seventy-two analyses, performed on consecutive days, of the urine of a gouty patient; and the results exemplified, in a marked manner, the peculiar mode in which uric acid is frequently eliminated in such cases, and also tended to confirm the conclusions arrived at with respect to the action of colchicum upon the excretion of this principle.

A paper by Mr. J. Priduck was then read,

#### ON THE IODIDE OF CALCIUM.

The object of this short paper was to bring before the Society a new preparation of iodine in combination with Hæc. The history of the salt and the mode of preparing it, its solution, and some of its compounds, with other articles of the

*Materia Medica*, were published in the *Lancet* of Dec. 8th, 1855. Since that time it has been used extensively in public and private practice, with satisfactory results. It had not been brought forward with a view to supersede the valuable preparations of iodine already in use, but as a preparation which might be used in cases wherein the iodide of potassium was inadmissible. Its advantages were: that the solution given in milk was tasteless; that being readily decomposed by the weak acid of the stomach, it was presented for absorption in a state of atomic division; that it did not excite the circulation, nor irritate the stomach and bladder by passing off too rapidly by the kidneys; that it did not occasion iodism nor resorption of the healthy tissues. The diseases for which it had been successfully prescribed by the author, besides those strumous affections for which the other preparations of iodine were generally used, were: chronic catarrh and bronchitis; incipient phthisis; squamous diseases of the skin; chronic metallic poisoning by mercury, lead, and copper. Under its administration the gums had become healthy, the fetor of the breath had been removed, the neuralgic pains had been relieved, and the patient's health had been restored. The forms in which it had been prescribed were: the simple solution; the solution and compound fluid extract of *sarsaparilla*, and fluid extract of dandelion; the solution and tincture of sesquichloride of iron; and with other tonic and bitter vegetable infusions not containing starch.

A paper Mr. D. F. RENNIE was read, entitled

#### OBSERVATIONS RELATING TO EXCESS OF DIET AS A CAUSE OF DISEASE, AND ON ITS CONNECTION WITH A HITHERTO UNRECOGNISED HYPERTROPHIC CONDITION OF THE LUNGS.

In this paper the author stated that he was first led to an investigation of this subject on entering upon his duties as Surgeon to the Convict Establishment at Fremantle, in June, 1863, by noticing a remarkable prevalence of cutaneous eruptions and other affections which were entirely confined to the convicts, the explanation of which he discovered in their excessive diet, which consisted, among other articles, of 27 ozs. of bread, 16 ozs. of fresh meat, daily, some of the men being allowed even more, and each prisoner had also a daily allowance of  $\frac{1}{2}$  oz. of tobacco. It was noticed that the re-convicted prisoners, who had less diet and no tobacco, suffered far less than the general body of the prisoners. It appears that defective means of restraint was, in a great measure, the cause of this great allowance of food being continued by the convict authorities, on the ground that it facilitated their control by moral force. In December of the same year ophthalmia and dysentery began to appear, and these, too, only among the prisoners, and for the most part taking the place of the cutaneous diseases, leading to the inference that they were mere local varieties of a general constitutional disorder, and, in most instances, were cases of pure metastasis of the cutaneous eruptions. The troops and population generally were entirely free from these complaints, so that there could be no reasonable doubt that they originated in the diet being in excess of the systemic demand; and it must be borne in mind, that from October to May the temperature in Western Australia is almost tropical. Under these circumstances, he (Dr. Rennie) made strong remonstrances on the subject; but the convict authorities being unable to comprehend the scientific principles involved in the adaptation of diet to climate, and taking as a precedent the very large diet given in the English prisons, as well as being strongly prepossessed against any reduction of the scale on disciplinary grounds, received his suggestions unfavourably. The result was, that during the year 1864, with a daily average of 706 prisoners, 2921 cases of sickness occurred, of which 1058 were treated in the hospital. Another urgent appeal was then made by Dr. Rennie, in which all the scientific bearings of the subject were fully discussed; and though the convict authorities still continued to oppose his views, Governor Fitzgerald ordered a Medical board for the consideration of the question. This board, of which the principal Medical officer was president, completely bore out the correctness of Dr. Rennie's objections to the diet, and recommended a gross weekly reduction of 136 oz. The reduction scale came into force on the 1st of June, 1865, and the results proved increasingly satisfactory, as there was abundant evidence, by statistical tables, to show.

Dr. Rennie, having arrived at the conclusion that the immediate cause of disease amongst the convicts in this colony was an excess of food operating on men with impaired constitutions, and consequently with impaired powers of digestion, devoted himself to an inquiry into the physical cause, which, he felt satisfied was developed previous to their arrival in that colony, and succeeded in identifying it with a hypertrophied condition of the pulmonary parenchyma, and a remarkably adherent state of the abdominal and thoracic viscera, generally unaccompanied by tubercular deposition, or any indications whatever of previous inflammatory action, and leading him to believe it to be a pure form of hyper-nutrition. The proofs and evidences which led to this conclusion were entered into at great length, as also the appearances, which, with few exceptions, were found in upwards of eighty post-mortem examinations. The portions of lung found most hypertrophied were the upper part of the right lung, and the lower portions behind. The lung tissue in these parts resembled the appearance described by Laennec as carnification, and at first the condition was viewed as one of chronic pneumonia, but this was disproved by the fact that it was present in nearly every case, and also that, almost without exception, the men so affected never had been, and were not at the time, affected with any symptom of chest disease. Dr. Rennie therefore attributed these abnormal symptoms and appearances to the prolonged operation of a diet too bulky and nutritious for the peculiar circumstances (hot cells and sedentary occupations) under which the convicts are placed during the earlier portions of their imprisonment in England. As the question has naturally presented itself as to whether these extraordinary appearances were developed before or after the prisoners landed in Western Australia, and with the view of ascertaining the condition of the respiratory organs, Dr. Rennie availed himself of the opportunity of examining upwards of fifty men immediately on their coming to shore, and in almost every case found a marked difference between the capacity of the two lungs for containing air, the functions of the right one being almost invariably most defective. In most cases there was, in addition, a general absence of healthy respiration, and, curiously, the more so in those men who had previously been totally free from chest diseases. All this, Dr. Rennie thinks, strikes at the root of the whole dietetic system pursued during the earlier period of their confinement in England, the state of these convicts with respect to sickness contrasting strongly with that of the inmates of the military prison, who have a simple, wholesome, and yet ample diet, and plenty of exercise in the open air; whereas the convicts, during the first twelve months of their imprisonment, are shut up like hot-house plants in a warm cell, employed at a sedentary occupation, and placed on a diet double that allowed to the military prisoners.

Dr. WEBSTER said that Dr. Rennie had laid down some novel principles in his paper. He agreed with him in thinking that the prisoners to whom he referred received too much animal food; but much would depend upon whether they had any hard labour to undergo, in which case the bad effects of the too nutritive diet would be counteracted. He did not agree with the author in thinking that prisoners in England were overfed. There was no class of persons so healthy as the criminals confined in London prisons; which, he believed, was greatly owing to the excellent diet. In Denmark the prisoners received no beef, but were given horse-flesh instead, and their health was very good.

Dr. MURCHISON suggested that the disease to which the prisoners in Australia were subject was of a tubercular nature, and occasioned by their close confinement.

Dr. BALY said the diet of the prisoners had been several times reduced, and was now assimilated to the diet in English prisons. Dr. Rennie desired a still further reduction, but this was not permitted. He could not agree in the conclusions of the author, who did not appear to be a careful observer. He did not believe that dysentery and constipation were produced by over-feeding. With regard to the adhesions to which reference had been made, they were not more frequent in convicts than in persons of the same class who died in hospitals, except so far as they might be produced by tubercular disease; and when that disease was discovered in the convict it was well known that an addition to the food would often arrest it. The author's account of what he had

denominated hypertrophy of the lungs was, he believed, incorrect; and he (Dr. Baly) regretted that such a paper should have been read before the Society.

## MEDICAL NEWS.

**ROYAL COLLEGE OF SURGEONS.**—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at the meeting of the Court of Examiners on the 18th inst. :—

ARMSTRONG, LUKE, Newcastle.  
CARTER, ALBERT FLEYDELL, Gloucester.  
EVANS, THOMAS, Carmarthen.  
HOSKINS, E. J., North Perrott, Crewkerne, Somerset.  
JAMES, RICHARD, Narberth, Pembrokeshire.  
JOHNSON, WILLIAM SETON, Maidstone, Kent.  
M'FADDEN, JOHN, Convooy, county of Donegal.  
NICHOLSON, WILLIAM HUNTER, Old-street, St. Luke's.  
OLDHAM, CHARLES FREDERICK, Liverpool.  
PEARCE, CHARLES WORTHAM, Peterborough.  
SMITH, JOSEPH, Birmingham.  
STOCKER, RICHARD C. S., Baker-street, Portman-square.  
TRIFE, WILLIAM BORROWDALE, Commercial-road-east.  
WHALLEY, WILLIAM, Keighley, Yorkshire.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, June 17, 1858 :—

ADSETTS, JOHN, Derby.  
CHAPMAN, CHARLES EDWARD, Preston, Lancashire.  
CREW, JOHN, Tetbury, Gloucestershire.  
DOBSON, WILLIAM C., Hamilton-terrace, Highbury.  
EWEN, ARTHUR BENJAMIN, Lang Sutton, Lincolnshire.  
RAND, JOHN, Hadleigh, Suffolk.  
REES, HARDING, Beaconsfield.  
ROBINSON, ENOCH, Marsden, near Huddersfield.

## DEATHS.

CLARKE.—April 5, at Melbourne, Arthur Clarke, M.R.C.S., late of St. Thomas's Hospital and Westcott, near Dorking, aged 24.  
FOLKARD.—On the 17th June, at his residence, North-street, Brighton, D. M. Folkard, aged 66.  
HAMMOND.—On the 7th ult., at Bagdad, Frederick Kaimes Hammond, H.E.I.C., late of Southampton.  
MAUND.—April 3, at Melbourne, Victoria, John Maund, M.D., Physician to the Melbourne Lying-in Hospital, and Medical Jurist to the Supreme Court of Victoria, aged 35.  
PHIPPS.—June 14, at the Curragh Camp, Kildare, William Henry Phipps, Assistant-Surgeon 2nd Battalion Coldstream Guards, aged 27.

## APPOINTMENTS.

The Queen has been pleased to appoint Nathan Lewis Young, M.D., to be a member of the Council of Barbadoes. Mr. S. A. Cusack has been appointed one of the Assistant-Surgeons to Stevens' Hospital, in the room of the late Dr. Harrison; and Mr. Edward Hamilton succeeds Mr. Cusack as House-Surgeon to the Hospital.

**THE VACCINATION ACT.**—In the Act passed on Monday, Medical officers are to be in future supplied with books and forms.

**UNIVERSITY COLLEGE.**—The Fellowes Clinical Medicine Prize of a gold medal has been awarded to Mr. William G. Groves, of Maidencombe, Teignmouth.

**UNIVERSITY OF DURHAM.**—Public Examinations, Easter Term, 1858.—For the degree of Bachelor of Medicine, William Young, licentiate in medicine.—At a convocation holden on Tuesday, June 15, the following degree was conferred :—Bachelor of Medicine, William Young, licentiate of medicine, Neville-hall.

**THE BLANE MEDALS.**—The Council of the Royal College of Surgeons, on the recommendation of Sir John Liddell, the Director-General of the Medical Department of the Royal

Navy, has awarded the gold medals founded by the late Sir Gilbert Blane, Bart., to the Naval Medical officer whose diary shall possess the greatest amount of scientific knowledge, to Dr. William Richard Edwin Smart, of her Majesty's ship *Diamond* (1855); and Dr. Alexander Eugene Mackay, of her Majesty's ship *Fantome* (1855).

**LUNATIC ASYLUMS.**—The number of licensed houses in England and Wales for the care of lunatics was, on the 1st of January, 1858, 113. In the licensed houses of the metropolis the total number of lunatics was 2623—viz. 1306 private and 1317 pauper patients. The sexes are pretty equal as regards the private patients, but among the paupers the number of the females exceeds the number of the males twofold. The total number of lunatics in the provincial licensed houses on the 1st of January was 2647—viz. 1497 private, and 1150 pauper patients.

**DEMORALIZING ADVERTISEMENTS.**—At a Meeting of the Halifax Board of Health, held May 10th, 1858, His Worship the Mayor in the chair, it was resolved, That this Board think it due to the conductors of the City Press, to acknowledge the readiness with which they have omitted the insertion of a certain class of profitable, but highly pernicious and objectionable quack advertisements, on its being privately represented to them that such advertisements were especially injurious to the morals and health of the community. It was further resolved, That a copy of the foregoing resolution be sent to the office of each of the city newspapers. Many of our own papers would add to their respectability by following this colonial example.

**IMITATION OF THE NATURAL PRODUCTION OF PEARLS.**—At a *soirée* at St. Bartholomew's Hospital on the 16th instant, Mr. Quekett exhibited some very interesting specimens illustrating the manner in which pearls were produced naturally, and the manner in which the natural production might be artificially imitated. He showed that the oyster-shell was first perforated from without by a boring-worm, and when the inner layer is reached, this layer is pushed inwards, covered with lustrous coating of the shell, and at length detached. The introduction of wires and other foreign bodies from without imitated the action of the borer, and the body became coated or plated with the pearly layer. This is doubtless important in a commercial point of view.

**INOCULATION OF SMALL-POX.**—Another death from the above cause has recently occurred in the county of Kilkenny, in the person of a child named Patrick Fletcher. The parents had been at their work at Chapel Izod, when the deceased was inoculated by a man named Mackey, who makes this pernicious practice his means of livelihood. This quack was expected to visit the district on the day in question, and the mother, on leaving home to go to her work, left a shilling for him to have the deceased "cut for the pock." A coroner's inquest was held, when the jury found a verdict against Mackey, as also against the mother, Margaret Fletcher, for aiding and assisting in the outrage. The coroner issued a warrant against Mackey for manslaughter, and took bail for the appearance of Margaret Fletcher to stand her trial, for aiding him, at the assizes. When the coroner had concluded his investigation, Mr. Izod addressed the persons present in a very forcible manner, giving a history of the practice of vaccination, pointing out its good results, and the baneful and criminal effects attending inoculation for the small-pox.

## TO CORRESPONDENTS.

Mr. Adams's paper on Tracheotomy shall appear immediately.

Mr. Harper.—The blame rests with the College, for not sending correct lists to the Journals.

F.R.S.—Her Majesty has recently allotted a suite of apartments at Hampton Court to Professor Faraday.

M.D.—General Peel is the proper person to present officers in the army officially at Court; but Medical officers are frequently presented by the Director General.

G.L.P.—It is to be hoped that whatever Bill may pass, some punishment will be inflicted upon those who falsely represent themselves as possessors of Medical diplomas.

A. Suckling.—"Electrolytes" are substances directly decomposable by electricity. The term "electrode" is synonymous with "pole." "Bio-gas" is another term for physiology (Bios, life).

**A Medical Coroner.**—According to the new Act the coroner must furnish the Registrar with the particulars of each inquest; but the Coroner need not sign the register as heretofore.

**Gen. Pract.**—Larten's cod-liver oil jelly is made with 60 parts of cod-liver oil, 10 of spermaceti, 25 of simple syrup, and 25 of rum. They are all rubbed up together until they acquire a gelatinous consistence. Chevalier's formula is as follows:—Dissolve 16 parts of gelatine in 125 parts of boiling water, then add 125 parts of simple syrup, 250 parts of cod liver oil, and enough of some aromatic oil (cinnamon, lemon or clove), to flavour the mixture. The mixture is to be poured, while cooling, into a wide-mouthed bottle.

#### "FRIGHTFUL DEATH FROM FRIGHTFUL SURGERY."

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Such is the heading of a case recorded in the Jersey papers; and as such you call to it the attention of the Profession in your Journal of the 19th.

Allow me, Sir, under the same heading, and through your columns, to ask the Edinburgh periodical sectionists, what was the cause of the death in Edinburgh on the 10th inst. of a gentleman of this neighbourhood, whose loss, at 31 years of age, has filled this place with mourning and regret?

I am, &c.

A SALISBURY MAN.

#### CONSTANT GALVANIC CURRENT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Mr. H. W. Lobb (Medical Times, No. 412) in his reply to Dr. Althaus, states that, if I failed to cure paralysis with the constant current, I might succeed with rheumatism, chorea, etc., because they are antagonistic affections. Mr. Lobb, after his own observations believes "that the continuous current will be found more useful and manageable than the induced current; both are valuable, the induced in paralysis, the constant in neuralgia, rheumatism, cramps, chorea, and in all hyperaesthesiae."

Though I feel satisfied that the constant current has found an impartial defender in your country, I cannot but observe, that, if the effects of the constant current are, as I have observed in so many cases, so superior to those of the induced current in antagonistic affections, the "means of application of the current are also no less different and their effects antagonistic" in different kinds of diseases, as I shall have occasion to explain in my work now in the press. Especially I hope to show that the constant current is a better anti-paralytic remedy than has hitherto been known.

I am, &c.

ROBERT REMAK.

Berlin, 18th May, 1858.

#### MEDICAL ETHICS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Can you or any of your readers inform me what is the proper course to pursue in such circumstances as the following:—

A Medical man, in daily attendance on a patient, on visiting him on a certain day is informed that, three days before, another Medical man had been requested to see the patient; that, on the previous day, this Medical man had called, and "knowing that another was in attendance," had examined and prescribed for the patient, and said, that he would be glad to meet the original attendant next day for consultation.

Ought the original attendant to consent to this consultation, or ought he not rather to resign the case into the hands of the other? And, if he consent to the consultation, hoping that some explanation and apology would be made by the other Medical man, and receives none, ought he to consent ever again to meet that Medical man in consultation?

I am, &c.

DELTA.

[Our correspondent has only half stated his case. He says nothing of his wishes of the patient.—Ed.]

#### THE COLLEGE LISTS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In the last number of the *Medical Times* you have published a list of gentlemen, commencing with Barley, D. B., and terminating with Teevan, W. F., who are stated to have been admitted "Members," it should have been "Fellows," of this College by examination.

In consequence of several inquiries here, I beg you will make the necessary alteration next week.

I am, &c.

EDWIN BELFOUR, Secretary.

Royal College of Surgeons, London, W.C., June 21, 1858.

[If Mr. Belfour would do as the Secretaries of all the Universities and Colleges, except the College of Surgeons, do, and send correct pass-lists to the Medical Journals, such mistakes would not occur. The blame rests solely with the College. Gentlemen aggrieved by inaccuracy would do well to inquire if the Council or the Secretary are responsible for the neglect.—Ed.]

#### CONSTANT GALVANIC CURRENT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I am sorry I have to intrude again upon your valuable space, but as Dr. Remak's reply to my letter on the "Constant Galvanic Current" imputes to me a hostile spirit, from which I feel myself totally free, and calls in question the correctness of one of my statements, which I still consider as perfectly true, I trust you will allow me to say a few words in reply.

1. Dr. Remak's assertion that the induced current cannot be applied to the living body without producing a weakening effect, has not been proved, and cannot be proved, as it is contrary to experience.

2. Dr. Remak's method of treatment has not been successful when brought under the notice of the Profession at Paris.

3. History proves that the continuous galvanic current has been applied to the treatment of nervous diseases by other physiologists and physicians a long time before Dr. Remak. (Cf. Guitard's History of Medical Electricity, and Becquerel's Treatise on the Application of Electricity to Therapeutics.)

4. As to the alleged successful treatment of inflammation of the spinal cord by the continuous galvanic current, I am afraid Dr. Remak has been mistaken in the diagnosis of his cases.

I am, &c.

2, Manchester-street, June 21, 1858.

J. ALTHAUS, M.D.

#### A GOOD EXAMPLE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Great liberties being sometimes taken with Medical men by people having a high opinion of their own importance, and whose time is seldom very valuable, the following anecdote respecting Dr. Keim, who was court physician at Berlin during the first quarter of the present century, may be quoted as an excellent illustration of such Teutonic propensities. Among the nobility in Germany, and especially aions of Royalty, it is customary often to address parties not belonging to their exclusive circles, in the third person singular. Against this absurd system, Dr. Keim always objected strongly, of which an instance may be here related, when he was appointed physician in ordinary to the Princess Ferdinand of Prussia, a haughty personage, and an inveterate stickler for ancient aristocratic usages. Before the worthy doctor would accept the proffered appointment, he insisted upon three conditions:—1. That his patient should always address him by the word *you*, not *he*. 2. That he must never be made to kick his heels by waiting in the ante-chamber, as then some patients would certainly suffer, by his not keeping other engagements. And 3. That he should be *royally* remunerated, although her Royal Highness was said to be very avaricious. However, as the Princess valued her health even more than money, and would have Dr. Keim as her professional attendant, the greedy lady succumbed also on this important point, and ever afterwards became the steady patroness of her much valued physician.

I am, &c.

M.D.

June 21, 1858.

#### THE MARSHALL HALL METHOD OF TREATING APNŒA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I have much pleasure in acknowledging the courteous letter which appeared in your Journal for this week, June 12, from a "Second Coadjutor in Dr. Hall's experiment," with reference to my method of treating persons apparently drowned or dead. I beg to assure him that I am perfectly conversant with the contents of Dr. Hall's work on Drowning. I am sorry to be obliged to refer to the experiments there described,—no doubt "the experiments performed by Mr. Hunter and other gentlemen at St. George's Hospital on the dead subject," appeared to them to prove "that nearly as much air entered the lungs as would be inhaled in an ordinary inspiration in a state of health," taking our average at thirty cubic inches. I think there must be some fallacy here, (perhaps from one-thirtieth to one-fourth part of one cubic inch would be more nearly the amount of air inhaled in the postural method, so far as I am at present able to judge.) The method of performing the experiments just mentioned is by no means satisfactory, and is I believe open to obvious objections. The tube of the pneumometer was passed into one nostril of the patient, the other nostril and the lips being closed by adhesive plaster. The want of rigidity of the cheeks, and the amount of air in the respiratory tract, and even in the stomach, etc., of the patient, could scarcely fail to render the indications of the instrument, even if perfect in itself, liable to suspicion, if not entirely valueless in point of scientific accuracy. Hence my reason for connecting the instrument with the trachea.

Any objection which might be urged from the presence of rigor mortis does not affect the results of my experiments, as I have been careful to draw practical deductions from those cases only in which the observations were made when the body was quite warm, and within one hour and a half after death.

The occasional position of the epiglottis resting against the back of the pharynx is simply an anatomical fact.

I am, &c.

HENRY R. SILVESTER, B.A., M.D. Lond.

High-street, Clapham, June 16, 1858.

COMMUNICATIONS have been received from—

Dr. MCWILLIAM; REGISTRAR GENERAL; Mr. WILLIAMS; Dr. REMAK, Berlin; Dr. ALTHAUS; Mr. TEEVAN; SECRETARY GENERAL BOARD OF HEALTH; Dr. THOMSON; Mr. STEVENS; Mr. BARRETT; Dr. LEUBUSCHER, Berlin; Mr. ADAMS; Mr. W. ADAMS; G. L. P.; Mr. Salt; M.A.B.; Mr. CATTLIN.

## APPOINTMENTS FOR THE WEEK.

June 26. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m.; Charing-Cross, 1 p.m.

28. Monday.

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.; Orthopedic Hospital, 2 p.m.

29. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

30. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Orthopedic Hospital, 2 p.m.

July 1. Thursday.

Operations at St. George's, 1 p.m.; Middlesex, 12½ p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m. Zoological Society, 3 p.m.

2. Friday.

Operations at the Moorfields Ophthalmic, 10 a.m.; Westminster Ophthalmic, 1½ p.m.; Great Northern, 2 p.m.

## EXPECTED OPERATIONS.

King's College Hospital.—The following operations will take place this day (Saturday), at 2 o'clock:—

Staphylosaphy; hare-lip; removal of dead bone from femur. By Mr. Ferguson.

Westminster Hospital.—The following operations will take place on Tuesday next, at 2 o'clock:—

Resection of elbow-joint; excision of mamma; application of actual cautery for lupus. By Mr. Holt.

END OF VOLUME XXXVII.

LONDON:

PRINTED BY CHARLES REED AND BENJAMIN PARDON,  
 LOVELL'S-COURT, PATERNOSTER-ROW.

## Struve's Seltzer, Fachingen, Marien-

BAD, VICHY, and other MINERAL WATERS. Royal German Spa, Brighon. Under Her Majesty's especial patronage. Struve's Pump Room and Promenades, for the perfect dispensing of the most renowned Continental Mineral Waters, is NOW OPEN for the Thirty-fourth Season. The bottled Mineral Waters are sold throughout the year at the Pump Room, and by George Waugh and Co., Pharmaceutical Chemists to the Queen, 177, Regent-street (west side), London; and other respectable Chemists in London and the provincial towns, where a Prospectus, with the highest Medical testimonials, may be obtained, gratis.

CAUTION.—To distinguish these from all other Waters, each bottle is secured by a label and red-ink stamp, bearing Struve and Co.'s name.

## The Medicated Cod Liver Oils,

In a genuine state, are prepared only in SAVORY and MOORE'S Laboratory.—This class of Medicines now numbers upwards of twenty, of which the following are principally prescribed:—

- Cod-liver Oil with Quinine.
- Cod-liver Oil with Iodide of Iron, Lactate of Iron, and Acetate of Iron.
- Cod-liver Oil with Iodine, and Iodide of Potassium.
- Cod-liver Oil with Biniodide of Mercury.

SAVORY and MOORE'S "LIQUOR PEPSINÆ" offers a most efficacious and agreeable mode of administering PURE PEPSEIN. All NEW REMEDIES which are recognised by the Medical Profession are kept or promptly prepared in the Laboratory, at 143, New Bond-street.

## James's Powder.—Physicians and

other Medical Practitioners having complained of the frequent use of Antimonial Powder, instead of the genuine "James's Powder," prescribed, have represented to Messrs. Newbery, that the price of the powder has greatly led to this fraudulent practice, and has also greatly prevented the more general use of the powder. Messrs. Newbery have therefore yielded to the suggestions of the Profession, and have reduced the price; and, to secure the use of the genuine medicine, recommend that the same should be prescribed as prepared by Messrs. Newbery, from the only copy of the process left by Dr. James in his own handwriting, thus, "Pulv. Jacobi Ver." (Newbery's.) The price for dispensing will henceforth be reduced from 21s. to 9s. an ounce. The genuine has the name, "F. Newbery, 45, St. Paul's, London," engraved on the Government Stamp.

## Great Saving in the Purchase of Six

GROSS of NEW MEDICAL GLASS BOTTLES and PHIALS, assorted to suit the convenience of Purchasers, at ISAACS and SON, Medical Glass Bottle Manufacturers.—London Warehouses, 24 and 25, Francis-street, Tottenham court-road, London, W.

A remittance not required till the goods are received. Packages free. Delivered free within seven miles. Post-office Orders payable to "S. Isaacs and Son," at Tottenham-court-road. Bankers: Unity Bank.

## Great Reduction in the Prices of New

MEDICAL GLASS BOTTLES and PHIALS, at the Islington Glass Bottle Works, Islington-place, Park-road, London Warehouses, 19, Broad-street-hill, Upper Thames-street, City, and 2, Upper Copenhagen-street, Barnsbury-road, Islington.

E. and H. HARRIS and Co. beg to submit the following prices, for quantities of not less than 6 gross, assorted to suit the convenience of the purchaser.

	8s.	per gross.
6 & 8 oz., any shape, plain or graduated	8s.	per gross.
3 & 4 oz. do.	7s. 6d.	do.
1/2 oz. white moulded phials	4s. 6d.	do.
1 oz. do.	5s. 6d.	do.
1 1/2 oz. do.	6s.	do.
2 oz. do.	7s.	do.

Immediate attention to country orders. No remittance required until the goods are received. Packages free. Goods delivered free within 7 miles. Post-office orders made payable to E. and H. HARRIS and Co., at the Chief Office, London. Bankers: Union Bank of London.

N.B.—Orders sent to either of the above establishments will meet with prompt attention.

## The Sydenham Trousers, 17s. 6d.;

COATS, 33s.; and WAISTCOATS, 8s. 6d.—It is well known how great an influence is exercised upon the health by the mode of dress. Many disorders, and still more of the common indispositions or irregularities, can be distinctly traced to imperfect adaptation of the clothes to the functions of the body and the limbs. This is true of adults as well as of children, though, perhaps, not to the same extent. The Sydenham construction of the whole attire is directed to secure a perfect fit in all positions without restraint, strain, or incumbrance, so that the limbs retain as free play as if in PURIS NATURALIBUS. The Boy's Complete Suit (24s.) is also eminently adapted for these purposes. The material and workmanship are the best which can be commanded. The assortment open for selection is immense, and includes all that is most fitted for the season. The assortment of Sydenham Alpaca Overcoats (12s. 6d.) for Summer wear deserves attention, as these goods have been made with unusual care.

SAMUEL BROTHERS, Merchant Tailors, 29, Ludgate-hill.

## Carriages, New and Second-hand, of

superior style, sterling quality, and finest finish at reasonable rates, for cash, credit, job, or exchange. Circular of prices on application. Credit given when required. Buyers should take carriages on trial, with power to purchase by yearly payments, and thus prove them.

OFFORD'S PATENT MEDICAL MAN'S BROUGHAM MANUFACTORY, 79, WELLS-STREET, OXFORD-STREET.

BROUGHAMS.

## Kinder, M'Naught, and Smith,

MANUFACTURERS, WORCESTER, beg respectfully to invite the attention of professional men to their improved Medical Broughams, as under:—

Width of Seat.	Weight.	Price.
3 ft. 5 in.	7 1/2 cwt.	85 Guineas.
3 ft. 6 in.	8 cwt.	95 Guineas.
3 ft. 7 in.	9 cwt.	100 Guineas.

The latter, including a segmental front, with seat for third person. These Carriages are constructed, by the aid of machinery, of the best material, are of excellent workmanship, and particularly adapted to the wants of medical men, either in town or country. Drawings and other particulars forwarded on application.

## Condy's Patent Fluid contains nascent

Oxygen, which is NATURE'S DISINFECTANT, for instantly and permanently removing all unpleasant smells. It has no smell—is not poisonous—will not stain when diluted—may be used for purifying water for drinking. Its colour prevents the possibility of mistake in use. It is recommended by the General Board of Health, &c. &c.

Sold by the Trade in bottles, at 6d., 1s., and 2s. each, or at 5s. per gallon.—1 gallon mixed with 200 gallons of water, makes a strong disinfecting fluid, costing one farthing per gallon.

MANGANATE or PERMANGANATE OF POTASH as ESCHAROTICS. Central Retail Depot, 97, Fleet-street, London, E.C., whence samples of 1 dozen 3-pints, or 4 dozen 1-pint, or 4 dozen quarts of the Fluid, and 4 oz. or upwards of the Manganates or Permanganates, will be forwarded, carriage paid, to any part of the kingdom, at the retail prices, on receipt of stamps for the amount.

This is notified, in case of any difficulty in obtaining either of these substances through the usual sources.

Wholesale of the Patentee, Battersea, Surrey, S.W.

## Williams and Son's Pure Glycerine

SOAP. Analysed by Dr. Hofmann, F.R.S., and Professor Redwood, Ph.D., strongly recommended by many eminent members of the Medical Profession, and favourably noticed by the following Medical Journals:—

- THE LANCET.
- THE MEDICAL TIMES AND GAZETTE.
- THE BRITISH MEDICAL JOURNAL.
- THE MEDICAL CIRCULAR.
- EDINBURGH MEDICAL JOURNAL.
- THE DUBLIN HOSPITAL GAZETTE.

It is suited to all cases of delicate skin (whether arising from disease or otherwise), and is admirably adapted for nursery use. May be had of all respectable Chemists, Perfumers, &c.

SOAP-WORKS, CLERKENWELL, LONDON, E.C.

## The Best Food for Children, Invalids,

and others.—ROBINSON'S PATENT BARLEY, for making Superior Barley-Water in Fifteen Minutes, has not only obtained the Patronage of Her Majesty and the Royal Family, but has become of general use to every class of the community, and is acknowledged to stand unrivalled as an eminently pure, nutritious, and light food for Infants and Invalids; much approved for making a delicious Custard Pudding, and excellent for thickening Broths or Soups.

ROBINSON'S PATENT GROATS, for more than thirty years, have been held in constant and increasing public estimation, as the purest farinæ of the oat, and as the best and most valuable preparation for making a pure and delicate GRUEL, which forms a light and nutritious supper for the aged, is a popular recipe for colds and influenza, is of general use in the sick chamber, and, alternately with the Patent Barley, is an excellent Food for Infants and Children.

Prepared only by the Patentees, ROBINSON, BELVILLE, and CO., Purveyors to the Queen, 64, RED LION-STREET, HOLBORN, LONDON.

Sold by all respectable Grocers, Druggists, and others, in town and Country, in Packets, at 6d. and 1s., and in Family Canisters, at 2s., 5s., and 10s. each.

## Crosse and Blackwell, Purveyors in

Ordinary to Her Majesty, respectfully invite attention to their PICKLES, Sauces, Tart Fruits, and other table delicacies, the whole of which are prepared with the most scrupulous attention to wholesomeness and purity. The practice of colouring pickles and tart-fruits by artificial means has been discontinued, and the whole of their manufactures are so prepared that they are not allowed to come in contact with any deleterious ingredient. A few of the articles most highly recommended are, Pickles and Tart Fruits of every description, Royal Table Sauce, Essence of Shrimps, Soho Sauce, Essence of Anchovies, Jams, Jellies, Orange Marmalade, Anchovy and Bloaters Pastes, Strasbourg and other Potted Meats, and Cal's-Foot Jellies of various kinds for table use. C. and B. are also sole agents for M. Boyer's Sauces, Relish, and Aromatic Mustard; and for Carstairs' Sir Robert Peel's Sauce, and Payne's Royal Osborne Sauce. The above may be obtained of most respectable Sauce Vendors throughout the United Kingdom; and Wholesale of

CROSSE and BLACKWELL, 21, Soho-square.
